1. EXECUTIVE SUMMARY

Cross-Spectrum Acoustics (CSA) was retained by the Vermont Department of Public Service (the Department) to provide sound monitoring expert services for the Deerfield Wind Project (the Project) located in Searsburg and Readsboro, Vermont. The Project's Certificate of Public Good (CPG) contains conditions limiting sound emissions from the Project and requiring submission of a sound monitoring plan to be implemented during the first full year of operation. Sound monitoring is to take place under the direction of the Department and must be conducted in accordance with the "Final Sound Monitoring Protocol for Deerfield Wind"¹ (the Protocol). Pursuant to the Protocol, monitoring is required to consist of two continuous periods, each of two to five weeks duration, with one during the fall and one during the spring. The purpose of the monitoring program is to determine whether the Project is operating in compliance with the sound monitoring standards set forth in its CPG.

CSA completed the fall 2018 monitoring program over a period of five weeks from October 22 until November 26, 2018 with measurements conducted at three locations, designated as Sites A, B, and C. The methodology and findings previously were presented in the final report for the fall measurement program².

CSA completed the spring 2019 monitoring program over a period of five weeks from May 8 until June 12, 2019. Approximately 595 hours of raw data were collected at Site A over 25 days; approximately 380 hours of data were collected at Site B over 16 days; and approximately 790 hours of data were collected at Site C over 35 days. Following the methodology provided in the Protocol, CSA analyzed the measurement data with respect to the CPG's standards for prominent discrete tones, A-weighted exterior sound levels, and A-weighted interior sound levels. The conclusions for each standard are as follows:

- *Prominent Discrete Tones:* The entire monitoring period at each measurement site was evaluated for prominent discrete tones. No occurrences of prominent discrete tones associated with the Project were identified during the spring 2019 monitoring period.
- *A-weighted Exterior Sound Levels:* Using the methodology provided in the Protocol, exterior "turbine-only" sound levels were calculated from measured "turbine-on" and "turbine-off" sound levels. For the spring monitoring period, computed "turbine-only" sound levels at all measurement sites complied with the CPG's exterior sound level limit.
- *A-weighted Interior Sound Levels:* Interior "turbine-only" sound levels were calculated from measurements of exterior "turbine-on" and "turbine-off" sound levels and the assumption of a fixed Outdoor-to-Indoor Noise Reduction (OINR) of 15 dB to the A-weighted exterior sound level. For the spring monitoring period, the computed "turbine-only" sound levels at all measurement sites complied with the CPG's interior sound level limit.

In summary, based on the measurements and analysis conducted in accordance with the Protocol and described in this report, we conclude that the Deerfield Wind Project complies with all aspects of the CPG's sound level limits for the spring 2019 monitoring program.

2. INTRODUCTION

This section provides an introduction to the sound monitoring compliance report and includes the Project's background, a brief introduction to the fundamentals of sound and noise descriptors, and a discussion of the Project's noise standards.

2.1. PROJECT BACKGROUND

CSA was retained by the Department to provide sound monitoring expert services for the Deerfield Wind Project located in Searsburg and Readsboro, Vermont. The Project was approved by the Vermont Public Utility Commission (PUC, formerly the Public Service Board) in Docket 7250 on April 16, 2009 and commenced operations late in 2017. The CPG, issued April 16, 2009 and amended July 17, 2009, contains conditions limiting sound emissions from the Project, and requiring submission of a sound monitoring plan to be implemented during the first full year of operation. Sound monitoring is to take place under the direction of the Department and must be conducted in accordance with the Protocol approved by the PUC in Docket 7250 in January 2018. (The Protocol is attached to this report as Appendix A.)

The Protocol requires monitoring to consist of two continuous periods, each of two to five weeks duration, with one during the fall and one during the spring. This report describes the methodology and findings of the spring 2019 monitoring period. The remainder of the report provides a brief introduction to understanding environmental noise, describes the applicable Project noise standards as set forth in the CPG, describes the methodology used in the sound monitoring and data analysis, provides the results of the second (spring 2019) period of sound monitoring, and provides conclusions based on the monitoring results.

2.2. NOISE FUNDAMENTALS

Sound is defined as vibrations that travel through the air or another medium and can be heard when they reach a person's or animal's ear. Noise often is defined as unwanted sound. All sounds may be characterized by three parameters:

- **Level:** Sound is transmitted through the air in sound waves comprised of small oscillations in pressure just above and below atmospheric pressure. Sound pressure *level* is expressed in decibels (dB), a logarithmic quantity based on the sound pressure of the sound source of interest and a reference pressure representing the quietest sound we can hear. Although humans can detect sound levels from close to 0 dB (the lower limit of human hearing) to approximately 120 dB without experiencing pain, most environmental sounds fall within a range between about 30 dB and 100 dB.

Because decibels are logarithmic quantities, sound pressure levels do not combine, or add, as we might expect. For example, combining two sound sources that each generate a sound pressure level of 40 dB individually causes a total sound pressure level of 43 dB (not 80 dB). Every doubling of source strength results in an increase of 3 dB, so that four 40-dB sources have a combined sound pressure level of 46 dB, eight 40-dB sources have a combined sound pressure level of 49 dB, etc. A tenfold increase in either the source strength or number of equivalent sources causes the sound pressure level to increase by 10 dB.

If a louder noise source and a quieter noise source operate simultaneously, the louder source will dominate the overall sound pressure level. For example, if a 20-dB source is added to a 40-dB source, the quieter source will add less than 0.1 dB to the louder source, resulting in a combined sound pressure level that still is approximately 40 dB. As the quieter source gets louder, however, its effect on the combined sound pressure level will increase. If the quieter source increases until it is equal to the louder source, it will add 3 dB to the combined sound level, resulting in an overall sound level of 43 dB.

In a related fashion, humans also perceive changes in sound pressure level logarithmically. Generally, a change in sound level of 6-10 dB may be perceived as a doubling (or halving) of the sound level. Changes in sound level of less than 3 dB change are difficult to perceive in an environmental setting.

- **Frequency:** Frequency (pitch) is related to the rate of the small oscillations in air pressure that we perceive as sound, and is expressed in cycles per second, or Hertz (Hz). Human ears can detect a wide range of frequencies from around 20 Hz to 20,000 Hz when we are young, but the upper limit tends to decrease to about 10,000 Hz to 15,000 Hz as we age. Because human hearing is less sensitive at very high and low frequencies, the A-weighting system, which emphasizes mid-range frequencies between about 500 Hz and 10,000 Hz, was developed to correlate with human response to noise. The A-weighted sound level has been widely adopted by acousticians as the most appropriate descriptor for environmental noise. Sound levels that have been measured using A-weighting typically are expressed as “A-weighted decibels” (dBA), or indicated with a subscript such as L_{AS} (A-weighted “slow response” sound pressure level). Figure 1 provides examples of A-weighted sound levels for some typical environmental noise sources.

(Source: Federal Transit Administration, 1995)

Figure 1. Typical A-weighted Environmental Sound Levels

- **Time Pattern:** Because environmental noise changes continuously, it is sometimes convenient to describe a particular noise event or source in terms of its maximum sound level ($L_{\max}$ or $L_{A\max}$). While the maximum sound level is useful in describing one aspect of an event or noise source, it provides no information on the duration of the event or the cumulative exposure to a noise source. A common way to account for the cumulative exposure is to express the energy-average of the actual time-varying sound level over a period of time as a single number, called the “equivalent” sound level (L_{eq} or $L_{A\text{eq}}$). The L_{eq} is the constant or “equivalent” sound level that would contain the same amount of sound energy as the time-varying sound level over the same period. Due to the logarithmic addition of noise sources described above, L_{eq} is influenced strongly by the loudest events that occur during a particular period. Because the L_{eq} represents the changing sound level over a specific interval, such as one hour, an eight-hour workday, or the nine-hour nighttime period from 10:00 PM until 7:00 AM, it is important that the time period be expressed or understood when using the metric.

2.3. PROJECT NOISE STANDARDS

The purpose of the monitoring program is to determine whether the Project is operating in compliance with the sound monitoring standards set forth in its CPG. The CPG conditions relevant to Project noise standards are as follows:

Deerfield shall construct and operate the Project so that the turbines emit no prominent discrete tones pursuant to ANSI standards at the receptor locations; and Project-related sound levels at any existing surrounding residences do not exceed 45 dBA (exterior) (L_{eq} , 1 hour) or 30 dBA (interior bedrooms) (L_{eq} , 1 hour).

Each of these requirements is discussed below in greater detail.

2.3.1. Prominent Discrete Tones

The presence of prominent discrete tones for this project was based on ANSI Standard S12.9-2005 Part 4, Annex C³, which provides the following guidance to test for tonal content:

The test for the presence of a prominent discrete-frequency spectral component (tone) typically compares the time-average sound pressure level in some one-third-octave band with the time-average sound pressure levels in the adjacent two one-third-octave bands. For a prominent discrete tone to be identified as present, the time-average sound pressure level in the one-third-octave band of interest is required to exceed the time-average sound pressure level for the two adjacent one-third octave bands by some constant level difference. The constant level may vary with frequency. Possible choices for the level differences are 15 dB in low-frequency one-third-octave bands (25-125 Hz), 8 dB in middle frequency bands (160-400 Hz), and 5 dB in high-frequency bands (500-10,000 Hz).

The analysis in this report was conducted using the ANSI Standard’s suggested “possible choices” for level differences.

2.3.2. A-weighted Exterior Sound Levels

The CPG for the Project requires that project-related exterior sound levels at any existing surrounding residences do not exceed 45 dBA (exterior) (L_{eq} , 1 hour). Because it is not possible to measure project-related sound levels directly in the presence of other background noise sources, the Protocol provides a

³ ANSI S12.9-2005/Part 4, *Quantities and Procedures for Description and Measurement of Environmental Sound, Part 4: Noise Assessment and Prediction of Long-Term Community Response*, Annex C: Sounds with tonal content, American National Standards Institute, Inc., 2005.

procedure for determining project-related sound through related measurements. The procedure requires separate measurements of two different quantities: overall sound levels (i.e. background sound plus project-related sound) and background-only sound levels (i.e. with use of all project-related equipment curtailed). The background sound level then is subtracted logarithmically from the overall sound level to determine the project-related exterior sound level.

2.3.3. A-weighted Interior Sound Levels

“Because the 30 dB interior limit established by the PUC is sufficiently low that the sound test is easily contaminated by normal activities that occur indoors” and, additionally, because “frequent sound monitoring inside a bedroom is intrusive,” the Protocol limits sound tests of turbine operations to exterior measurements, with interior sound levels calculated based on a fixed 15 dBA reduction.⁴ Homeowners, however, have the option to request testing to determine the actual outside to inside noise reduction (OINR) of their house if the home meets either of the following criteria:

- The preconstruction sound model shows Deerfield Project sound levels of 40 dBA or higher at that location; or
- Sound monitoring (post-construction) shows Deerfield Project sound levels of 40 dBA (L_{eq})(1 hr) or higher at that location.

3. METHODOLOGY

This section of the report provides an overview of the required methodology as provided in the Protocol. The Protocol provides an outline of the required methodology for both the field measurements and the data processing related to the sound monitoring program. The “Noise Monitoring Plan for Deerfield Wind Project, Final, Revised,”⁵ (“Monitoring Plan,” attached to this report as Appendix B), originally developed for the fall 2018 measurements, provides additional details regarding the logistics of the measurements. Although the methodology used for the spring 2019 measurements was similar, several changes were made due to different conditions during the spring measurement period and site-specific experience gained during the fall 2018 measurements. Each of these changes is described below in Section 3.1.

Both the Protocol and the Monitoring Plan may be consulted for further details beyond the overview provided here.

3.1. CHANGES IN METHODOLOGY COMPARED TO FALL 2018

This section of the report describes the changes in methodology between the fall 2018 and spring 2019 measurements.

3.1.1. Relocation of Site A

During the fall 2018 measurements, Site A was positioned at the location of a house that had previously burned down. When the owner was contacted prior to the start of the spring 2019 measurements, CSA was informed that construction of a new house would occur during the period of the spring measurements. To ensure that the measurement equipment would not interfere with construction activities, Site A was relocated to another position on the same property approximately 150 feet to the north/northeast. Compared to the original site, any difference in distance to the nearest turbines (over 3,700 feet away) was negligible and screening provided by terrain was similar. Because the Protocol requires that all measurements used for compliance assessment occur between 10:00 PM and 7:00 AM, it was determined to be unlikely that noise from construction activities would interfere with the

⁴Protocol, Section 2.5 “Outside to Inside Test,” p. 6.

⁵“Noise Monitoring Plan for Deerfield Wind Project, Final, Revised,” Prepared for: Vermont Department of Public Service; Prepared by: Cross-Spectrum Acoustics, Inc., October 17, 2018.

measurements. In addition, any construction activities that did occur during those hours would be readily identified through the measurement data and accompanying audio recordings. Although the relocated site was closer to VT Route 9 than the original site, all vehicle passbys were filtered from the measurement data and, therefore, did not affect the measurement results. All docket parties were informed of the proposed change by email and provided an opportunity to comment prior to the start of the spring measurements.⁶ Section 3.2.2 of the report provides further information on both the original and relocated site and a figure showing both measurement locations.

3.1.2. Addition of Site C-Alt

Site C is the closest of the three measurement sites to the separate Searsburg Wind Energy Facility operated by Green Mountain Power. Because the Searsburg turbines are not part of the Deerfield Project, they remained in operation during the Deerfield curtailments conducted during the fall 2018 measurements and influenced background sound levels at Site C. During the fall 2018 measurements, it was determined that the proximity of Site C to the Searsburg turbines was the primary reason for the relatively small difference between the “turbine-on” and “turbine-off” sound levels at this site.⁷

As described in Section 3.3.2 of this report, the Protocol requires that when “background sound levels are within 3 dB of the adjacent measured Turbine-on sound levels, the background and Turbine-on periods will be excluded from further processing.”⁸ Although this criterion resulted in the exclusion of some data at all three monitoring sites during the fall 2018 measurements, the issue was most prevalent at Site C, where it caused the exclusion of nearly 10 hours of otherwise valid “turbine-on” data. Consequently, despite conducting the maximum five weeks of monitoring mandated by the Protocol at Site C, the required threshold of two hours of valid data was not achieved at Site C during the fall 2018 measurements.

To address this issue prior to the spring 2019 measurements, the Department submitted a motion to the PUC to modify the Protocol for the spring 2019 measurements, and the motion was granted by the PUC on April 25, 2019. The modification added a supplementary measurement location for the spring 2019 measurements, with monitoring conducted both at Site C and a new Site C-alt. In accordance with the modified Protocol, “Site C-alt would be in close proximity to Site C, and would be flush-mounted on the outer wall of a building on the west side facing away from the Searsburg wind turbines.”⁹ The purpose of Site C-alt was to provide measurement data obtained at a location close to the original Site C, but largely shielded from sound generated by the Searsburg turbines. Data from Site C-alt were to be utilized only if insufficient data were obtained at the original Site C. Ultimately, sufficient valid data were collected at Site C during the spring 2019 measurements, and the Site C-alt data were not used in the analysis or reporting. Section 3.2.2 of this report provides additional information on Site C-alt.

3.1.3. One-minute Weather Monitoring Intervals

During the fall 2018 measurements, in accordance with the Protocol’s requirements,¹⁰ meteorological equipment at Site B included a weather station which logged temperature, precipitation, wind speed, and wind direction over 10-minute intervals. Also in accordance with the Protocol, meteorological equipment at Site A and Site C included anemometers and wind vanes which logged wind speed and direction over 10-minute intervals. Subsequent to the fall 2018 measurements, Deerfield’s consultant, RSG,

⁶ Email from Allison Wannop, Subject: “Deerfield Wind Spring Sound Monitoring: Update on Site A,” May 2, 2019.

⁸ Protocol, Section 3.0 “Data Processing,” p. 9.

⁹ “Order Granting Motion to Modify the Sound Monitoring Protocol and Deferring a Decision on Thomas Shea’s Request for Outdoor/Indoor Noise Reduction Testing,” State of Vermont Public Utility Commission, p. 3, April 25, 2019.

¹⁰ Protocol, Section 2.4 “Logistics,” p. 5.

recommended increasing the wind speed logging frequency from 10-minute intervals to 1-minute intervals. CSA considered this recommendation and agreed to do so for the Spring 2019 measurements.¹¹ The primary benefit of the shorter logging frequency was potentially to provide more valid data by having the option to exclude measurement intervals shorter than 10 minutes due to weather conditions.

3.1.4. ANS-weighting

In some situations, natural sounds such as birds, insects, and frogs may influence background sound levels measured in natural and quiet outdoor areas. The Protocol recognizes this and permits the filtering of such sounds by employing a low pass filter (i.e. a filter which excludes high frequencies) which the Protocol advises may be used “without affecting the sound monitored from the turbines.”¹² Although the Protocol provides a reference for so-called “Ai-weighting” of measured sound levels,¹³ an American National Standard to address this issue has been developed jointly by the American National Standards Institute (ANSI) and the Acoustical Society of America (ASA).¹⁴ The resulting standard, which was based on Ai-weighting, defines the “ANS-weighted sound level” and provides guidance for its use.

In addition to defining the ANS-weighted sound level and providing guidance for its use, the Standard also provides a comparison of the A-weighted and ANS-weighted sound levels for various noise sources in the absence of natural sounds. For “general community noise,” the average ANS-weighted sound level has been shown to be 1.0 dB lower than the A-weighted sound level. For “fan noise” the average ANS-weighted sound level has been shown to be 0.8 dB lower than the A-weighted sound level.¹⁵

During the fall 2018 measurements, there was little nocturnal bird, insect, or frog activity; therefore ANS-weighting was not utilized. During the spring 2019 measurements however, ANS-weighting was used, to some extent, at Sites A, B, and C. At Site A and Site B, ANS-weighting was most often used to filter out bird songs between approximately 4:00 AM and 7:00 AM. At Site C, due to the presence of a small pond near the measurement site, frogs often were active throughout the night, and ANS-weighting was used more extensively.

In all cases, if it was necessary to use ANS-weighting for any portion of a particular curtailment (i.e. any portion of either the turbine-off or turbine-on periods), then ANS-weighting was used for the entire curtailment. This approach ensured that the comparison of turbine-on and turbine-off sound levels to determine the required 3-dB difference would always use the same metric for all data associated with a single curtailment. In all cases, the report distinguishes between the use of A-weighted and ANS-weighted sound levels.

3.2. FIELD MEASUREMENTS

3.2.1. Monitoring Periods

The Protocol requires that the fall and the spring monitoring periods each have a minimum continuous duration of at least two weeks, but may be extended for up to five weeks, if necessary, to obtain sufficient data. The spring 2019 measurements began at all sites on Wednesday, May 8. After confirming that sufficient valid data had been collected, measurements were concluded at Site B on Friday, May 24. At Site A, after confirming that sufficient valid data had been collected, measurements were concluded on

¹⁵ *Ibid.*, Annex A.

Sunday, June 2. Measurements at Site C continued for the full five-week period, concluding on Wednesday, June 12.

3.2.2. Monitoring Locations

The Protocol describes the general locations for the three required sound monitoring sites and also states “where monitoring locations are near residential areas, to the extent permission is granted, monitors shall be set near individual homes closest to the Project at these locations. If permission is not granted, then alternative homes shall be contacted, or monitors will be placed in public rights-of-way that are representative of a home, at a similar or lesser distance from the Project.”¹⁶ Based on this guidance and using aerial photo imagery, CSA first selected several candidate locations for each monitoring site prior to the fall 2018 measurement program. CSA then conducted visits to the project area on October 1, 2018 and October 16, 2018 to field check the candidate sites. Following the site visits, and after receiving additional input from docket holders, CSA selected the three final sites to be used in both the fall 2018 and spring 2019 monitoring periods.

The three final sites were selected based upon the guidance in the Protocol; conditions on the ground, including accessibility and distance from local noise sources such as roads; and the ability to gain permission from property owners. In all cases, in accordance with the Protocol, sites were selected that were “at least 7.5 m from any surface where reflections could influence measured sound pressure levels” and were placed in locations “to avoid potential contamination from sources such as flowing water, wind chimes, air conditioners, noise from homes, etc.” In addition, sites were selected such that no “structure blocks the line of sight between the microphone and the wind turbines (if otherwise visible).” Finally, CSA made “every reasonable effort to site microphones in a manner that will maximize the probability of capturing the maximum noise levels at each monitoring location, taking into account all relevant factors such as minimizing line-of-sight obstructions between microphone and the Project, and maximizing the number of turbines in line-of-sight of the microphones at each monitoring location.”¹⁷

For the spring 2019 measurements, the locations of Site B and Site C were the same as those used for the fall 2018 measurements. As described above in Section 3.1.1, due to construction activity at the former house location used during the fall 2018 measurements, Site A was relocated approximately 150 feet to the north/northeast. Both the distance and line-of-sight to the nearest wind turbines were comparable at the two locations. As described in Section 3.1.2, measurements also were conducted at a supplemental measurement site located on the same property as Site C. The measurement data collected at this location (Site C-alt) were not used in the analysis because a sufficient amount of valid data was obtained at the original Site C.

Figure 2 provides an overview map showing the general location of each measurement site and the locations of the Project’s 15 turbines. Following the figure, Table 1 provides a general description of each measurement site’s location, the approximate latitude and longitude of the site, the property owner, and other relevant notes.

The following text offers further information on each monitoring site, and Appendix C provides field data sheets for each measurement location, including site sketches.

Figure 2. Noise Monitoring Sites and Project Wind Turbines

Table 1. Spring 2019 Monitoring Sites

Monitoring Site	Location	Lat./Long.	Owner	Notes
Site A (Relocated)	South of Old Route 9 and VT Route 9	42.89102 -73.00001	James Bartleson	House shown in aerial imagery no longer present
Site B	197 VT Route 8	42.88178 -72.97244	Gerry DeGray	Clearing to south side of house and driveway
Site C	343 VT Route 8	42.87274 -72.97124	Tom Shea	Edge of graded area south of barn
Site C-alt	343 VT Route 8	42.87286 -72.97122	Tom Shea	Flush-mounted on west exterior wall of barn

Site A: The Protocol describes Site A as “located south of Old Route 9, east of Bishop Hill Road, and south of VT Route 9 in Searsburg. This site is similar in location to Site 2 from the preconstruction monitoring.”¹⁸ For the fall 2018 measurements, the actual location selected for Site A was on the former site of a house located off of Old Route 9 and approximately 600 feet south of the centerline of VT Route 9, south of the transmission line right of way. The microphone was located approximately 110 feet southwest of the nearest utility pole. This location was representative of several homes located on Old Route 9 and represents the closest homes to the northwest of the Project’s western group of turbines (indicated on Figure 2 as W-01 through W-08), with the nearest turbine approximately 3,700 feet to the southeast. As described above in Section 3.1.1, for the spring 2019 measurements Site A was relocated approximately 150 feet to the north/northeast of the original site. Non-project noise sources at this location included traffic on VT Route 9, natural sounds, including birds and wind in trees, and occasional aircraft overflights. Figure 3 shows the locations of both the original and relocated Site A. Figure 4 and Figure 5 provide photos of the relocated Site.

Figure 3. Site A Location Map

¹⁸Protocol, Section 2.3 “Microphone Locations,” p. 3.

Figure 4. Site A (Relocated), View to North

Figure 5. Site A (Relocated), View to Southeast

Site B: The Protocol describes Site B’s location as “near the transmission line that crosses VT Route 8 approximately 1.3 km (0.8 miles) south of the VT 8/VT 9 intersection in Searsburg and west of VT Route 8. This site is similar to Site 4 from the preconstruction noise monitoring.”¹⁹ The selected location for Site B was a private residence at 197 VT Route 8, which is the first residence south of the transmission line right of way. The microphone was located approximately 175 feet from the centerline of VT Route 8. This site represented the closest homes to the east of the Project’s western group of turbines, with the nearest turbine approximately 3,700 feet to the west-northwest. Non-project noise sources at this location included traffic on VT Route 8, activities at the residence such as yardwork and vehicles entering and leaving the driveway, natural sounds, including wind in trees, birds, frogs, and insects, and occasional aircraft overflights. Figure 6 shows the location of Site B. Figure 7 and Figure 8 provide photos of the site.

(Basemap Google, 2018)

Figure 6. Site B Location Map

¹⁹Protocol, Section 2.3 “Microphone Locations,” p. 4.

Figure 7. Site B, View to Northeast

Figure 8. Site B, View to Northwest

Site C and Site C-alt: The Protocol describes Site C as “approximately 0.5 miles north of Sleepy Hollow Road on VT Route 8 in Searsburg, west of Route 8. This site is similar to Site 5 from the preconstruction monitoring.”²⁰ To be consistent with the Protocol’s guidance that “monitors shall be set near individual homes closest to the Project,”²¹ the actual monitoring site was located farther north, approximately 0.9 miles north of Sleepy Hollow Road, at the private residence at 343 VT Route 8. This site represented the closest homes to the east of the Project’s western group of turbines along this portion of VT Route 8 and was among the closest to the Project’s eastern group of turbines (indicated on Figure 2 as E01 through E-07). The microphone was located approximately 240 feet from the centerline of VT Route 8 and the closest Project turbines were approximately 4,100 feet to the west-southwest (W-04 and W-05) and approximately 6,000 feet to the south-southeast (E-01). In addition, the closest turbines in the Searsburg Wind Energy Facility operated by Green Mountain Power were approximately 4,100 feet to the southeast of this site. Non-project noise sources at this location included traffic on VT Route 8, the Searsburg wind turbines, activities at the residence such as vehicles entering and leaving the driveway and construction on some days, natural sounds, including frogs, birds, and wind in the trees, and occasional aircraft overflights.

As described above in Section 3.1.2, for the spring 2019 measurements an additional measurement site (Site C-alt) was added near Site C. The purpose of Site C-alt was to obtain supplemental data in a location largely shielded from sound caused by the Searsburg Wind Project turbines. The supplemental data from Site C-alt were to be examined only if the original Site C did not provide sufficient valid data. Because sufficient data were obtained at Site C, the data from Site C-alt were not utilized.

Figure 9 shows the locations of both Site C and Site C-alt. Figure 10, Figure 11, Figure 12, and Figure 13 provide photos of the two measurement sites.

3.2.3. Instrumentation

Sound Monitoring Equipment

Sound level measurements were conducted at each site using NTi XL-2 portable sound level meters, which meet the ANSI and IEC standards for Class 1 “Precision” sound level meters. With the exception of Site C-alt, microphones, with seven-inch hydrophobic windscreens, were mounted on tripods approximately five feet above ground level. At Site C-alt, the microphone was flush-mounted on a sheet of reinforced ¾-inch plywood approximately five feet above ground level and was equipped with a hemispherical seven-inch hydrophobic windscreen. The plywood sheet was secured to an existing building with clamps. All meters were field calibrated at the start and the conclusion of the measurements and at intervals of every two to four days throughout the monitoring period. In addition, all instruments used for the measurements previously had been calibrated by an independent laboratory with certification traceable to the National Institute of Standards and Technology (NIST). The sound level meters were programmed to collect 1/3 octave band data at one second intervals and to log additional sound level data over 10-minute intervals. In addition, audio recordings were made throughout the monitoring period at all three sites.

Meteorological Equipment

Meteorological equipment at Site A and Site C included anemometers and wind vanes mounted on approximately five-foot high tripods, similar to the height of the nearby microphones. This equipment logged wind speed and direction over 1-minute intervals. At Site B, meteorological equipment included a weather station which logged temperature, precipitation, wind speed, and wind direction over 1-minute intervals. The sensors for the weather station were mounted on an approximately five-foot high tripod.

Appendix D provides a list of all instrumentation used at each site.

3.2.4. Background Sound Measurements

The Protocol requires that background sound levels must be measured by curtailing operation of the wind turbines at regular intervals, thus allowing a direct comparison between periods with and without turbines operating. To accomplish this, all Project turbines and ancillary equipment were shut down throughout the monitoring program for at least 20 minutes at a time, no less than once per night (10 PM to 7 AM) when hub-height speeds were 6 m/s or above and there was no precipitation in the form of rain, sleet, or ice. Additionally, CSA requested Avangrid to monitor hub-height wind speeds for one hour prior to and one hour after each curtailment. Data were considered for further processing only from curtailments during which hub-height wind speeds for the entire period, beginning one hour before and extending for one hour after the curtailment, were 6 m/s or greater.

During the spring 2019 measurement program, Avangrid conducted a total of 20 curtailments on 12 separate nights. Each of these curtailments met the requirements described above. Sound level data from the curtailments were subjected to further filtering and data processing as described below in Section 3.3.2 of this report. Table 2 provides a summary of the curtailments. Appendix E provides 10-minute interval wind speed and electrical output data for each of the 15 Project turbines throughout the monitoring period.

3.2.5. Attended Measurement

The Protocol requires attended monitoring to take place at each monitoring location for one hour before or after at least one turbine shutdown event, with observers making time-stamped notes regarding what they hear and the relative loudness of those sounds. CSA conducted attended monitoring for a period of nearly four hours extending from 10:00 PM on May 21 until approximately 1:45 AM on May 22. During this period, CSA observers were at all three sites for two 20-minute curtailments (attempts number 10 and 11 shown in Table 2) and also one hour before and after the first shut-down and one hour before the second shut-down. Appendix F provides the observer logs for the attended measurements.

Table 2. Deerfield Wind Operational Curtailments, May 8 – June 12, 2019

Attempt Number	Start Date & Time ¹	End Date & Time ¹	Wind speed 6 m/s or higher for entire curtailment + 1 hour before and 1 hour after?
1	May 17, 11:11 PM	May 17, 11:31 PM	Yes
2	May 18, 1:31 AM	May 18, 1:51 AM	Yes
3	May 18, 3:51 AM	May 18, 4:11 AM	Yes
4	May 19, 5:25 AM	May 19, 5:45 AM	Yes

11	May 22, 1:20 AM	May 22, 1:40 AM	Yes
12	May 22, 3:40 AM	May 22, 4:00 AM	Yes
13	May 23, 1:24 AM	May 23, 1:44 AM	Yes
14 ²	May 23, 3:44 AM	May 23, 4:04 AM	Yes
15 ²	May 26, 12:08 AM	May 26, 12:33 AM	Yes
16	May 30, 5:16 AM	May 30, 5:36 AM	Yes
17	May 31, 4:10 AM	May 31, 4:30 AM	Yes
18	May 31, 11:23 PM	May 31, 11:58 PM	Yes
19	June 3, 1:21 AM	June 3, 1:41 AM	Yes
20	June 5, 1:30 AM	June 5, 2:00 AM	Yes
21	June 5, 4:35 AM	June 5, 5:00 AM	Yes
22	June 7, 11:34 PM	June 7, 11:55 PM	Yes
Notes: ¹ Curtailment start and end times in this table are nominal times provided by Avangrid and may differ from more precise times used in the data analysis. ² Curtailments 14 and 15 did not occur as initially reported by Avangrid. See Section 3.3.5 for further information.			

Source: Avangrid

3.3. DATA PROCESSING

During the spring 2019 monitoring period, approximately 595 hours of raw data were collected at Site A over 25 days, approximately 380 hours were collected at Site B over 16 days, and approximately 790 hours were collected at Site C over 35 days. This section of the report describes the methodology used to process the data and to perform the required evaluations of prominent discrete tones, A-weighted exterior sound levels, and A-weighted interior sound levels.

3.3.1. Prominent Discrete Tones

Using an automated process, the 1/3 octave band 10-minute interval data for the entire monitoring period at each measurement site were evaluated for prominent discrete tones. The evaluation was conducted in

accordance with the guidance from ANSI Standard S12.9-2005 Part 4, Annex C described above in Section 2.3.1 of this report and in Section 3.0 of the Protocol. Specifically, the Protocol requires that tonal sounds be evaluated “for each rolling measured Turbine-On $L_{eq(1-hour)}$ ” with rolling periods incremented every 10 minutes.²² Any tonal periods identified were then examined further to determine whether the source was related to the Project. Consistent with the practice described in the recent comprehensive *Massachusetts Study in Wind Turbine Acoustics*, the examination of tonal periods was limited to “the primary audible turbine frequencies ranging from 25 Hz to 1,000 Hz.”²³

3.3.2. A-weighted Exterior Sound Levels

As discussed above in Section 2.3.2 of this report, the Protocol recognizes that it is not possible to measure project-related sound levels directly due to the presence of other background noise sources, and, therefore, provides a procedure for determining project-related sound by comparing overall sound levels (i.e. background sound plus project-related sound) to background-only sound levels (i.e. with use of all project-related equipment curtailed). This section of the report further describes the methodology for determining project-related sound levels.

Periodically throughout the monitoring period, Avangrid provided 10-minute interval hub-height wind speed and power output data for all 15 turbines and also a log of any operational curtailments (i.e., “turbine-off” periods). The wind speed data from Turbines W-01 and W-08 were used to identify periods with acceptable hub-height wind speeds of 6 m/s or higher. These two turbines were selected as representing among the closest turbines to each of the measurement sites. Only periods with high enough wind speeds at both W-01 and W-08 were used in the analysis. After confirming that the wind speed was acceptable for each 20-minute “turbine-off” period, the 10-minute intervals for one hour before and one hour after each curtailment were screened, and any intervals during which the average wind speed was not at least 6 m/s at both W-01 and W-08 were excluded.

From this reduced data set, any periods with temperatures below 14° F, or with precipitation (including rain, sleet, and ice, but not snow) were excluded. For the remaining periods, any intervals during which the wind vector had a non-zero component from the monitoring site to the nearest turbine were considered “upwind” and were excluded. Any remaining intervals with maximum wind speeds above 5 m/s at each microphone were flagged for identification and exclusion during the secondary filtering. Similarly, intervals with maximum wind speeds between 4 m/s and 5 m/s were identified for further screening and possible exclusion. During the initial filtering, the presence of disqualifying weather data during any 1-minute interval was used to exclude the corresponding full 10 minutes of acoustic data. In some cases, during the subsequent, secondary filtering, the 1-minute weather data were used to exclude shorter intervals of acoustic data. Appendix G provides the results of the initial filtering, including which 10-minute intervals were excluded at each measurement site, along with the reason for the exclusion.

After the initial filtering, all remaining 10-minute periods were subject to secondary filtering using the 1-second acoustic data and 1-minute weather data. During the secondary filtering, any events exceeding 40 decibels (either A-weighted or ANS-weighted depending on the weighting applied for that curtailment) were investigated either by listening to the audio recording of the event, or by reviewing the spectrogram of the event, to determine if the cause of the event was related to the Project. Typical events eliminated from the data included traffic passbys and aircraft overflights. Although some noise caused by wind gusts was eliminated from the data, in general, noise caused by wind blowing in trees, etc. was not excluded from either the “turbine-on” or “turbine-off” data sets unless the wind gust either created pseudo-noise or wind-induced noise that was judged sufficient to mask wind turbine sound. As required by the Protocol,

²²Protocol, Section 3.0 “Data Processing,” p. 9.

²³ *Massachusetts Study on Wind Turbine Acoustics*, “Section 9.3, Tonality Under ANSI S12.9 Part 4,” Prepared for: Massachusetts Clean Energy Center and Department of Environmental Protection, Submitted by: RSG (Resource Systems Group, Inc.), February 18, 2016, p. 143.

all periods with wind speeds above 5 m/s at the microphone locations were excluded from the data, and periods with wind speeds between 4 m/s and 5 m/s were reviewed for possible wind contamination. Appendix H provides additional information on the secondary filtering for “turbine-off” periods and Appendix I provides similar information for “turbine-on” periods. In each case, the appendices provide graphs and tables identifying periods that were excluded, along with the reason for the exclusion.

Following the initial and secondary filtering described above, either the A-weighted or ANS-weighted L_{eq} was computed for the remaining portion of each qualifying “turbine-off” period. After filtering, the remaining “turbine-off” L_{eq} s used in the final computations ranged from approximately 11 to 30 minutes in duration. Similarly, either the A-weighted or the ANS-weighted L_{eq} was computed for the remaining portion of each qualifying 10-minute “turbine-on” interval within either one hour before or after the adjacent curtailment. Following filtering, the remaining portions of the “turbine-on” interval L_{eq} s used in the final computations ranged from approximately three minutes to 10 minutes in length.

The L_{eq} for each “turbine-on” interval then was compared to the L_{eq} for the adjacent “turbine-off” interval. The “turbine-on” L_{eq} was discarded if it was not at least 3 dB higher than the adjacent “turbine-off” L_{eq} . For this evaluation, CSA defined an “adjacent” interval as any 10-minute interval within either one hour before or one hour after the qualifying “turbine-off” period.

All remaining “turbine-on” periods were used to compute a single overall “turbine-on” L_{eq} for each measurement site. Similarly, all remaining “turbine-off” periods were used to compute a single overall “turbine-off” L_{eq} for each measurement site. The “turbine-off,” or background, energy-averaged sound level was then logarithmically subtracted from the “turbine-on” energy-averaged sound level to determine the “turbine-only” sound level at each measurement site. The computed “turbine-only” sound level is the appropriate value for comparison to the CPG limit.

3.3.3. A-weighted Interior Sound Levels

As described above in Section 2.3.3, the Protocol limits sound tests of turbine operations to exterior measurements, with interior sound levels calculated based on a fixed reduction in the A-weighted sound level of 15 dB. As an alternative to using the fixed 15 dB reduction, homeowners at locations where either the preconstruction sound model shows Project sound levels of 40 dBA (L_{eq})(1 hr) or higher, or where post-construction sound monitoring shows Deerfield Project sound levels of 40 dBA (L_{eq})(1 hr) or higher, may request Outdoor to Indoor Noise Reduction measurements. For the analysis of the spring 2019 measurements included in this report, A-weighted interior sound levels were calculated by applying a fixed OINR of 15 dB to the computed “turbine-only” sound level at each site.

3.3.4. ANS-weighted Sound Levels

As described above in Section 3.1.4, the Protocol permits the use of ANS-weighting in situations when natural sounds such as birds, insects, and frogs, influence the measured background sound levels. For the spring 2019 measurements, ANS-weighting was applied only during analysis of turbine shutdowns and the one-hour periods immediately preceding and following the shutdowns if such natural sounds were determined to be present and influencing the background sound level. In all cases, ANS-weighting was calculated in accordance with the applicable American National Standard for *Methods to Define and Measure Residual Sound in Protected Natural and Quiet Residential Areas*.²⁴ If it was found necessary to apply ANS-weighting for any portion of a particular curtailment (i.e. any portion of either the turbine-off or turbine-on periods), then ANS-weighting was used for the entire curtailment. This procedure ensured that the comparison of “turbine-on” and “turbine-off” sound levels to determine the required 3-dB difference would always be applied using the same metric for data associated with a single curtailment.

²⁴ ANSI/ASA Standard S3/SC1.100-2014 and ANSI/ASA S12.100-2014, American National Standards Institute/Acoustical Society of America.

Table 3 provides a summary of the curtailments and shows which weighting system (ANS-weighting or A-weighting) was used for each measurement site. Note that if use of ANS-weighting was not necessary, then the default A-weighting was used. The table shows that, to some extent, ANS-weighting was used at each of the measurement sites. At Site A and Site B, ANS-weighting was most often used to filter out bird songs between approximately 4:00 AM and 7:00 AM and was employed during only two curtailments at each site. At Site C, due to the presence of a small pond near the measurement site, frogs often were active throughout the night, and use of ANS-weighting was necessary during all except for one curtailment.

Table 3. Weighting System (A or ANS) Applied for Each Curtailment

Curtailment Number	Start Date & Time ¹	End Date & Time ¹	ANS- or A-Weighting		
			Site A	Site B	Site C
1	May 17, 11:11 PM	May 17, 11:31 PM	A	A	ANS

22	June 7, 11:34 PM	June 7, 11:55 PM	--	--	ANS
LEGEND: ANS ANS-weighting A A-weighting -- No acoustical analysis conducted (excluded by weather screening or after completion of measurements at Sites A or B) Notes: ¹ Curtailment start and end times in this table are nominal times provided by Avangrid and may differ from more precise times used in the data analysis. ² Curtailments 14 and 15 did not occur as initially reported by Avangrid. See Section 3.3.5 for further information.					

Source: Avangrid, CSA, 2019

Figure 14 provides an example comparing A-weighted and ANS-weighted data for the 10-minute interval starting at 4:50 AM on May 23 at Site A. The blue line shows the A-weighted 1-second time history; the yellow line shows the ANS-weighted 1-second time history for the same interval. In each case, the plotted sound levels were derived from the same measured acoustic data and the differences in the plotted data are the product only of the choice of ANS-weighting or A-weighting. The blue A-weighted line clearly shows the effects of early morning bird activity. Except for during two vehicle passbys on VT Route 9 (at approximately 4:53:30 and 4:56:30), the A-weighted sound level generally varies between about 35 dB and 50 dB. The yellow ANS-weighted line, which filters out the spikes caused by the bird songs, is confined to a smaller range, and (with the exception of the two vehicle events) varies only between approximately 33 dB and 37 dB.

Although the A-weighted and ANS-weighted sound levels are similar during the two vehicle passbys, in other periods with little or no apparent bird activity (e.g., 4:55:10 to 4:56:10), the ANS-weighted sound level is slightly lower than the A-weighted sound level, by about 0 to 1 dB. This is consistent with a comparison provided in the ANSI/ASA Standard of the A-weighted and ANS-weighted sound levels for various noise sources in the absence of natural sounds. For “general community noise,” the Standard states that the average ANS-weighted sound level has been shown to be 1.0 dB lower than the A-weighted sound level. Similarly, for “fan noise” the Standard states that the average ANS-weighted sound level has been shown to be 0.8 dB lower than the A-weighted sound level.²⁵

Figure 14. ANS-Weighting and A-Weighting Comparison

3.3.5. Periods Excluded Based on Turbine Data

As required by the Protocol, Avangrid provided 10-minute data, including wind speed and electrical output, for each turbine throughout the monitoring period.²⁶ Appendix E presents the complete set of data provided by Avangrid. During the ensuing data processing, several issues that potentially could affect the sound monitoring results were identified in the turbine data. CSA subsequently contacted Avangrid, and Avangrid confirmed each of the identified issues. In some cases, the issues were determined not to have a significant effect on the related sound monitoring data. In other cases, it was determined that the issues

²⁵ ANSI/ASA Standard S3/SC1.100-2014 and ANSI/ASA S12.100-2014, Annex A.

²⁶ Protocol, Section 4.0 “Reports,” p. 10.

identified in the turbine data may have influenced sound monitoring results. In the latter cases, all potentially-affected periods were excluded from the data analysis.

Each of the issues is identified below along with its resolution:

- *Issue 1:* After Curtailment 2, Turbine E4 did not come back online until approximately 6:50 AM on May 18, approximately five hours after the end of the curtailment. The extended shutdown of this turbine overlapped the hour of “turbine-on” data after Curtailment 2 and the hours of “turbine-on” data both before and after Curtailment 3.

Resolution of Issue 1: As shown on Figure 2, Turbine E4 is located near the center of the Project’s eastern turbine array. During the hour after Curtailment 2 and the one-hour periods both before and after Curtailment 3, the only valid data obtained and used in the analysis were from Site B. Because the other 14 Deerfield turbines were operating normally and because of Site B’s closer proximity to the western array, the absence of Turbine E4 affected the measured “turbine-on” sound levels at Site B by only an insignificant amount (no more than 0.1 dB). For these reasons, no data were excluded due to this issue.

- *Issue 2:* After Curtailment 5, Turbine E4 did not come back online until approximately 1:30 AM on May 20, approximately two hours after the end of the curtailment. The extended shutdown of this turbine overlapped the hour of “turbine-on” data after Curtailment 5.

Resolution of Issue 2: During Curtailment 5, the only valid data obtained and used in the analysis were from Site A. Because the other 14 Deerfield turbines were operating normally and because of Site A’s closer proximity to the western array, the absence of Turbine E4 affected the measured “turbine-on” sound levels at Site A by only an insignificant amount (no more than 0.1 dB). For these reasons, no data were excluded due to this issue.

- *Issue 3:* Before Curtailment 6, all turbines were offline for approximately 20 minutes, from approximately 2:55 AM to 3:15 AM on May 20. This offline period would have the potential to affect the hour of “turbine-on” data before Curtailment 6.

Resolution of Issue 3: All measurement data from the hour preceding Curtailment 6 were excluded from the analysis.

- *Issue 4:* After Curtailment 6, Turbine E4 did not come back online until approximately 6:50 AM on May 20, approximately two hours and 45 minutes after the end of the curtailment. The extended shutdown of this turbine overlapped the hour of “turbine-on” data after Curtailment 6.

Resolution of Issue 4: All measurement data from the hour after Curtailment 6 previously had been excluded from the analysis by the initial filtering for weather conditions. As a result, no additional data were excluded from the analysis due to this issue.

- *Issue 5:* After Curtailment 9, Turbine E4 did not come back online until approximately 6:20 AM on May 21, approximately 2 hours and twenty minutes after the end of the curtailment. The extended shutdown of this turbine would have the potential to affect the hour of “turbine-on” data after Curtailment 9.

Resolution of Issue 5: During Curtailment 9, the only valid data obtained and used in the analysis were from Site B. For reasons cited above, this issue affected “turbine-on” sound levels at Site B by only an insignificant amount (no more than 0.1 dB) and no data were excluded.

- *Issue 6:* After Curtailment 10, Turbine E4 did not come back online until approximately 5:50 AM on May 22, approximately six hours and 30 minutes after the end of the curtailment. The extended shutdown of this turbine overlapped the hour of “turbine-on” data after Curtailment 10 and the hours of “turbine-on” data before and after both Curtailment 11 and Curtailment 12.

Resolution of Issue 6: All measurement data from the hour after Curtailment 10 previously had been excluded from the analysis by the initial filtering for weather conditions. During Curtailment 11 and Curtailment 12, the only valid data obtained and used in the analysis were from Site B. For reasons cited above, this issue affected “turbine-on” sound levels at Site B by only an insignificant amount (no more than 0.1 dB) and no data were excluded.

- *Issue 7:* Curtailment 14 did not occur as initially reported by Avangrid.

Resolution of Issue 7: All measurement data related to Curtailment 14 were excluded from the analysis. Note that although this curtailment did not occur, it was retained in the list of curtailment attempts in Table 2 to maintain the original numbering sequence.

- *Issue 8:* Curtailment 15 did not occur as initially reported by Avangrid.

Resolution of Issue 8: All measurement data related to Curtailment 15 were excluded from the analysis. Note that although this curtailment did not occur, it was retained in the list of curtailment attempts in Table 2 to maintain the original numbering sequence.

- *Issue 9:* Before Curtailment 17, all turbines were offline for approximately 30 minutes, from approximately 3:20 AM to 4:00 AM on May 31. This offline period would have the potential to affect the hour of “turbine-on” data before Curtailment 17.

Resolution of Issue 9: All measurement data from the hour preceding Curtailment 17 previously had been excluded from the analysis by the initial filtering for weather conditions. As a result, no additional data were excluded from the analysis due to this issue.

4. MONITORING RESULTS

This section of the report provides the results of the monitoring and analysis for prominent discrete tones, A-weighted exterior sound levels, and A-weighted interior sound levels. As required by the Protocol, all turbine and background sound level values shown in this report are rounded to the nearest whole decibel.²⁷ Calculations were performed using the actual measured values, and the results rounded prior to inclusion in the report.

4.1. PROMINENT DISCRETE TONES

As described above in Section 3.3.1, the 1/3 octave band 10-minute interval data for the entire monitoring period at each measurement site were evaluated for prominent discrete tones. As required by the Protocol, the evaluation was conducted in accordance with ANSI Standard S12.9-2005 Part 4, Annex C “for each rolling measured Turbine-On $L_{eq}(1\text{-hour})$. . .” with rolling periods “. . . incremented every 10 minutes.”²⁸ The examination of tonal periods was limited to frequencies ranging from 25 Hz to 1,000 Hz.

Table 4 displays the results of the analysis.

²⁷Protocol, Section 3.0 “Data Processing,” p. 9

²⁸Ibid.

Table 4. Prominent Discrete Tones

Monitoring Site	Date	Time (Start of Rolling 1-hour L_{eq})	1/3 Octave Band Center Frequency	Source
Site A	5/10/2019	6:40 PM-7:20 PM	63 Hz	Electrical interference
Site A	5/11/2019	12:00 AM 1:30 AM-3:10 AM 3:40 AM 4:00 AM-8:20AM 6:20 PM-9:40 PM 10:50 PM-11:50 PM	63 Hz 63 Hz 63 Hz 63 Hz 63 Hz 63 Hz	Electrical interference
Site A	5/12/2019	12:00 AM-2:10 AM 6:40 AM-7:50 AM 9:00 AM-10:30 AM 2:20 PM-2:30 PM 10:20 PM-11:50 PM	63 Hz 63 Hz 63 Hz 63 Hz 63 Hz	Electrical interference
Site A	5/23/2019	12:40 PM 1:00 PM 1:10 PM 1:20 PM	100 Hz 100 Hz 100 Hz 100 Hz	Construction activity at residence
Site C	5/9/2019	9:50 AM 10:00 AM 10:10 AM	250 Hz 250 Hz 250 Hz	Electric saw
Site C	6/8/2019	10:00 AM 10:10 AM 10:20 AM 10:30 AM 10:40 AM 10:50 AM	200 Hz 200 Hz 200 Hz 200 Hz 200 Hz 200 Hz	Lawn mower
Site C	6/12/2019	11:00 AM	630 Hz	Motorized vehicle

At Site A, a 60-Hz tone occurred intermittently from the evening of May 10 through May 12. Because no turbine curtailments occurred during this period, the tone had no effect on the data analysis for the CPG sound level limits. Based on the 60-Hz frequency of this tone, and also due to the location of the measurement site near electrical transmission lines, it is likely that it was caused by electrical interference rather than an actual noise source. Had the tone been related to the Project wind turbines, it is likely that it would have been identified at another measurement site, or subsequently during the remainder of the measurements.

For the remainder of the five-week monitoring period, the analysis identified four events causing prominent discrete tones:

- At Site A, construction activity at the nearby residence caused a tone in the 100 Hz 1/3 octave band between approximately 12:40 PM and 1:20 PM on May 23.
- At Site C, a nearby electric saw caused a tone in the 250 Hz 1/3 octave band between 9:50 AM and 10:10 AM on May 9.

- At Site C, a lawn mower caused a tone in the 200 Hz 1/3 octave band on the morning of June 8. Although the event lasted for only 6.5 minutes, it influenced each of the rolling one-hour L_{eq} s starting at 10:00 AM, 10:10 AM, 10:20 AM, 10:30 AM, 10:40 AM, and 10:50 AM.
- At Site C, a motorized vehicle, such as a riding lawnmower, caused a tone in the 630 Hz 1/3 octave band. The duration of this event was three minutes and affected only the one-hour L_{eq} starting at 11:00 AM on June 12.

As none of these events was project-related, no occurrences of prominent discrete tones associated with the Project were identified during the spring 2019 monitoring period.

4.2. A-WEIGHTED EXTERIOR SOUND LEVELS

4.2.1. Summary

As described above in Section 3.3.2, A-weighted sound level data for qualifying “turbine-off” periods and adjacent qualifying “turbine-on” periods were evaluated in accordance with the Protocol. After filtering the data for required weather conditions and removing contaminating events, a single energy-averaged L_{eq} sound level was computed to represent the entire remaining “turbine-on” data at each site. Similarly, one energy-averaged L_{eq} sound level was computed to represent the entire remaining “turbine-off,” or background, data at each site. For each site, the background sound level then was subtracted logarithmically from the “turbine-on” sound level. The resulting “turbine-only” sound level then could be compared to the CPG’s exterior sound level limit. As discussed in Section 2.3.2, the CPG requires that project-related sound levels at any existing surrounding residences must not exceed 45 dBA (exterior) (L_{eq} , 1 hour).

Table 5 provides a summary of the analysis results. The computed “turbine-only” sound levels of 36 dBA at Site A, 40 dBA at Site B, and 38 dBA at Site C all comply with the CPG’s exterior sound level limit. The following sections of the report provide more in-depth discussions of the monitoring results at each of the three sites.

Table 5. Summary of A-weighted Exterior Sound Levels

Monitoring Site	“Turbine-on” Sound Level (L_{eq} , dBA)	“Turbine-off” Sound Level (L_{eq} , dBA)	“Turbine-only” Sound Level (L_{eq} , dBA)	CPG Exterior Sound Level Limit (L_{eq} , dBA)	Meets CPG Limit?
Site A	38	33	36	45	Yes
Site B	42	38	40	45	Yes
Site C	41	37	38	45	Yes

4.2.2. Site A

Sound level monitoring was conducted at Site A over a period of 25 days from May 8, 2019 until June 2, 2019. In addition, wind speed and wind direction data were collected at Site A throughout the same period. Temperature and precipitation data recorded at Site B were applied to this site. Figure 15 through Figure 18 provide graphs showing 10-minute interval data for L_{eq} sound level, wind speed, and temperature. The blue line indicates the A-weighted sound level throughout the entire measurement. The yellow segments indicate the A-weighted sound level during two curtailments when it was necessary to apply A-weighting, including one hour before and one hour after the turbine shutdowns. Each figure (except for the truncated weeks depicted in the first and final graphs) presents the data for a weeklong period and generally shows a typical diurnal pattern with the lowest sound levels occurring at night.

The highest measured sound levels at this site occurred during several periods on May 10, May 12, and May 13 and were caused by an unidentified source unrelated to the Project turbines. The unidentified noise source did not occur again after May 13 and did not affect any of the turbine curtailments used in

the analysis. Over the full monitoring period, 10-minute L_{eq} sound levels at Site A ranged from a low of approximately 28 dBA to a high of approximately 80 dBA. Excluding the unidentified noise source from May 10 until May 13, 10-minute L_{eq} sound levels for the remainder of the measurements ranged from a low of approximately 28 dBA to a high of approximately 73 dBA. Temperatures ranged from approximately -2°C to $+24^{\circ}\text{C}$ (28°F to 75°F) and 10-minute average wind speeds ranged from 0 m/s to approximately 5 m/s (0 mph to 11 mph). Brief pauses in data collection occurred every two to four days to download data, change batteries, and conduct calibration checks. In addition, approximately three hours of daytime data were lost on May 28 due to a battery failure.

Figure 15. Sound Level and Weather Data: Site A, May 8 – May 13, 2019

Figure 16. Sound Level and Weather Data: Site A, May 13 – May 20, 2019

Figure 17. Sound Level and Weather Data: Site A, May 20 – May 27, 2019

Figure 18. Sound Level and Weather Data: Site A, May 27 – June 2, 2019

During the monitoring period, six turbine-operation curtailments occurred with at least one 10-minute interval that satisfied the Protocol’s wind speed, wind direction, and temperature criteria for Site A. After further filtering and elimination of contaminating events, two hours and 21 minutes (141 minutes) of “turbine-on” data with an L_{eq} of 38 dBA, and 40 minutes of “turbine-off” data with an L_{eq} of 33 dBA remained. The computed “turbine-only” sound level of 36 dBA complies with the CPG’s 45-dBA standard. The filtered data exceeded the Protocol’s requirement of two valid hours of “turbine-on” data. The 25 days of measurements also exceeded the minimum requirement of two weeks of monitoring.

Figure 19 provides an example of typical sound level data at Site A associated with a turbine curtailment on May 19 and the adjacent one-hour periods before and after the curtailment. In contrast to the 10-minute L_{eq} data shown on the weekly graphs, this figure displays 1-second L_{eq} sound levels. Because of the presence of early morning bird activity, ANS-weighting was applied during the data analysis for this curtailment, and the plotted sound levels on Figure 19 are ANS-weighted. With the bird activity removed by the ANS-weighting, the remaining spikes in sound level are associated with individual vehicle passbys on VT Route 9. At this location, approximately 500 feet from the roadway, maximum passby sound levels generally ranged between about 48 to 63 dBA and occurred, on average, about every two minutes and 45

seconds (2:45 minutes) during this sample. During the intervals between vehicle passbys, the “turbine-on” sound level generally varied within a few decibels of 37 dBA. During the “turbine-off” period between approximately 5:25 AM and 5:50 AM, the background sound level between vehicle passbys dropped to roughly 34 dBA. Although the “turbine-on” and “turbine-off” sound levels shown in this example are consistent with the energy-average sound levels presented in Table 5, sound levels associated with other curtailments may be either higher or lower than the averages shown in Table 5.

Figure 19. Sound Level Time History Site A, May 19, 2019, 4:20 AM to 7:00 AM

4.2.3. Site B

Sound level monitoring was conducted at Site B over a period of 16 days from May 8, 2019 until May 24, 2019. In addition, wind speed, wind direction, temperature, and precipitation data were collected at Site B throughout the monitoring period. Figure 20 through Figure 22 present 10-minute interval data for L_{eq} sound level, wind speed, and temperature. As with the figures for Site A, the blue line indicates the A-weighted sound level throughout the entire measurement. The yellow segments indicate the ANS-weighted sound level during two curtailments, including one hour before and one hour after the turbine shutdowns, when it was necessary to apply ANS-weighting. Each figure (except for the truncated weeks depicted in the first and final graphs) presents the data for a weeklong period. Similar to Site A, the measured sound levels generally display a typical diurnal pattern with the lowest sound levels occurring during nighttime hours.

Over the full monitoring period, 10-minute L_{eq} sound levels ranged from a low of approximately 26 dBA to a high of approximately 64 dBA. Temperatures ranged from approximately -2°C to $+24^{\circ}\text{C}$ (28°F to 75°F) and 10-minute average wind speeds ranged from 0 m/s to approximately 3 m/s (0 mph to 7 mph). Brief pauses in data collection occurred every two to four days to download data, change batteries, and conduct calibration checks. In addition, approximately 12 hours of data were lost on May 19 due to a battery failure.

During the monitoring period, eight turbine-operation curtailments included at least one 10-minute interval that satisfied the Protocol’s wind speed, wind direction, and temperature criteria for Site B. After further filtering and elimination of contaminating events, three hours and forty minutes (220 minutes) of “turbine-on” data with an L_{eq} of 42 dBA, and one hour and forty-three minutes (103 minutes) of “turbine-off” data with an L_{eq} of 38 dBA remained. The computed “turbine-only” sound level of 40 dBA complies with the CPG’s 45-dBA standard. This filtered data exceeded the Protocol’s requirement of two valid hours of “turbine-on” data. The 16 days of measurements also exceeded the minimum requirement of two weeks of monitoring.

Figure 20. Sound Level and Weather Data: Site B, May 8 – May 13, 2019

Figure 21. Sound Level and Weather Data: Site B, May 13 – May 20, 2019

Figure 22. Sound Level and Weather Data: Site B, May 20 – May 24, 2019

Figure 23 provides an example of typical sound level data at Site B associated with a turbine curtailment that occurred on May 18, and the adjacent one-hour periods before and after the curtailment. Although hub-height wind speeds were at least 6 m/s throughout this sample, wind speeds at the measurement site initially were low and then increased in the hour following the curtailment. As a result, the final 30 minutes of the hour following the curtailment (2:40 AM to 3:10 AM) and several shorter periods in the 30 minutes immediately following the curtailment (2:10 AM to 2:40 AM) were excluded from the analysis due to wind gusts.

The 1-second interval L_{eq} sound levels shown on the figure indicate several individual vehicle passbys that occurred on VT Route 8 during the two-hour and forty-minute period. At this location, approximately 175 feet from the roadway, maximum passby sound levels during this sample ranged between about 50 and 60 dBA. During the majority of time when vehicles were not present in the hour prior to the curtailment, the “turbine-on” sound level typically varied between about 39 and 44 dBA. During the “turbine-off” period between approximately 1:30 AM and 2:00 AM, the background sound level varied between about 35 and 44 dBA. Although the “turbine-on” and “turbine-off” sound levels shown in this example are both generally consistent with the energy-average sound levels presented in Table 5, sound levels associated with other curtailments may be either higher or lower than the averages in Table 5.

Figure 23. Sound Level Time History Site B, May 18, 2019, 12:30 AM to 3:10 AM

4.2.4. Site C

Sound level monitoring was conducted at Site C over a period of 35 days from May 8, 2019 until June 12, 2019. In addition, wind speed and wind direction data were collected at Site C throughout the monitoring period. Temperature and precipitation data recorded at Site B were applied to this site. Figure 24 through Figure 29 provide graphs showing 10-minute interval data for L_{eq} sound level, wind speed, and temperature. Over the full monitoring period, 10-minute L_{eq} sound levels ranged from a low of approximately 28 dBA to a high of approximately 72 dBA. Temperatures ranged from approximately -2° C to +24° C (28° F to 75° F) and 10-minute average wind speeds ranged from 0 m/s to approximately 3 m/s (0 mph to 7 mph).

Figure 24. Sound Level and Weather Data: Site C, May 8 – May 13, 2019

Figure 25. Sound Level and Weather Data: Site C, May 13 – May 20, 2019

Figure 26. Sound Level and Weather Data: Site C, May 20 – May 27, 2019

Figure 27. Sound Level and Weather Data: Site C, May 27 – June 3, 2019

Figure 28. Sound Level and Weather Data: Site C, June 3 – June 10, 2019

Figure 29. Sound Level and Weather Data: Site C, June 10 – June 12, 2019

Brief pauses in data collection occurred every two to four days to download data, change batteries, and conduct calibration checks. In addition, on May 27, a remote cellular access module used to remotely check the meter at Site C malfunctioned and caused the meter to stop collecting data. The module was removed the followed day and the meter functioned normally for the remainder of the measurement period. No turbine curtailments occurred during the period when the monitoring was not functioning.

During the monitoring period, nine turbine-operation curtailments occurred with at least one 10-minute interval that satisfied the Protocol's wind speed, wind direction, and temperature criteria for Site C. After further filtering and elimination of contaminating events, two hours and ten minutes (130 minutes) of "turbine-on" data with an L_{eq} of 41 dBA, and 54 minutes of "turbine-off" data with an L_{eq} of 37 dBA remained. The computed "turbine-only" sound level of 38 dBA complies with the CPG's 45-dBA standard. The filtered data exceeded the Protocol's requirement of two valid hours of "turbine-on" data. The 35 days of measurements also exceeded the minimum requirement of two weeks of monitoring.

Figure 30 provides an example of typical sound level data at Site C associated with the turbine curtailment that occurred on May 19, and the adjacent one-hour periods before and after the curtailment. This figure shows the same curtailment depicted on Figure 19 for Site A. In addition to early morning bird activity, frogs tended to be present throughout most of the nighttime data at Site C. As with nearly all of the data at Site C, ANS-weighting was applied during the data analysis for this curtailment, and the plotted sound levels on Figure 30 are ANS-weighted. With bird and frog activity removed by the ANS-weighting for this curtailment, the remaining spikes in sound level are associated with individual vehicle passbys on VT Route 8. At this location, approximately 240 feet from the roadway, maximum passby sound levels during this sample generally ranged between about 49 and 61 dBA.

During the majority of time when vehicles were not present, the "turbine-on" sound level generally ranged from about 37 to 38 dBA for the first 30 minutes of the sample, and then increased to about 39 to 40 dBA for the 30 minutes immediately preceding the curtailment. During the "turbine-off" period between approximately 5:25 AM and 5:50 AM, the background sound level dropped to about 35 to 37 dBA. For the hour after the curtailment, the "turbine-on" sound level varied between about 40 and 41 dBA. Although the "turbine-on" and "turbine-off" sound levels shown in this example are roughly consistent with the energy-average sound levels presented in Table 5, sound levels associated with other curtailments at this site may be either higher or lower than the averages shown in Table 5.

Figure 30. Sound Level Time History Site C, May 19, 2019, 4:20 AM to 7:00 AM

4.3. A-WEIGHTED INTERIOR SOUND LEVELS

Table 6 provides a summary of the calculated interior sound levels at each of the three measurement sites. For each measurement site, the table shows the measured exterior “turbine-only” (i.e., “Project”) sound level, the assumed OINR of 15 dB, and the resulting interior “turbine-only” sound level, obtained by subtracting the assumed OINR from the exterior sound level. To comply with the CPG’s interior standard, the interior “turbine-only” sound level must not exceed 30 dBA (interior) (L_{eq} , 1 hour). The computed “turbine-only” interior sound levels of 21 dBA at Site A, 25 dBA at Site B, and 23 dBA at Site C all comply with the CPG’s interior sound level limit.

Table 6. Summary of A-weighted Interior Sound Levels

Monitoring Site	Exterior “Turbine-only” Sound Level (L_{eq} , dBA)	Assumed Outdoor to Indoor Noise Reduction (dB)	Calculated Interior “Turbine-only” Sound Level (L_{eq} , dBA)	CPG Interior Sound Level Limit (L_{eq} , dBA)	Meets CPG Limit?
Site A	36	15	21	30	Yes
Site B	40	15	25	30	Yes
Site C	38	15	23	30	Yes

5. CONCLUSIONS

The spring 2019 monitoring program was conducted over a period of five weeks from May 8 until June 12. The minimum requirement of two hours of valid “turbine-on” data was exceeded during 25 days of measurements at Site A, 16 days of measurements at Site B, and 35 days of measurements at Site C.

Based on the methodology provided in the Protocol, the measurement results at all three sites were analyzed with respect to the CPG’s standards for prominent discrete tones, A-weighted exterior sound levels, and A-weighted interior sound levels. The conclusions for each were as follows:

- *Prominent Discrete Tones:* The entire monitoring period at each measurement site was evaluated for prominent discrete tones in accordance with ANSI Standard S12.9-2005 Part 4, Annex C. No occurrences of prominent discrete tones associated with the Project were identified during the spring 2019 monitoring period.
- *A-weighted Exterior Sound Levels:* Using the methodology provided in the Protocol, exterior “turbine-only” sound levels were calculated from measured “turbine-on” and “turbine-off” sound levels. The CPG requires that project-related sound levels at any existing surrounding residences must not exceed 45 dBA (exterior) (L_{eq} , 1 hour). For the spring 2019 monitoring period, the computed “turbine-only” sound levels of 36 dBA at Site A, 40 dBA at Site B, and 38 dBA at Site C all complied with the CPG’s exterior sound level limit.
- *A-weighted Interior Sound Levels:* Interior “turbine-only” sound levels were calculated from measurements of exterior “turbine-on” and “turbine-off” sound levels and the assumption of a fixed OINR of 15 dB to the A-weighted exterior sound level. The CPG requires that project-related interior sound levels at any existing surrounding residences must not exceed 30 dBA (interior) (L_{eq} , 1 hour). For the spring 2019 monitoring period, the computed “turbine-only” sound levels of 21 dBA at Site A, 25 dBA at Site B, and 23 dBA at Site C all complied with the CPG’s interior sound level limit.

In summary, based on the measurements and analysis described in this report and conducted in accordance with the Protocol, we conclude that the Deerfield Wind Project complies with all aspects of the CPG’s sound level limits for the spring 2019 monitoring program.

---	----------

1.0 INTRODUCTION

The Vermont Public Utility Commission (“PUC” or “Commission”) (formerly the Public Service Board) issued a revised Certificate of Public Good (CPG) for the Deerfield Wind Project (Docket #7250) (the “Project”) on July 17, 2009. As part of the CPG, post-construction sound monitoring is required to assure conformance with the Project’s CPG noise standards. The conditions of the CPG related to the monitoring condition are:

28. Deerfield shall construct and operate the Project so that the turbines emit no prominent discrete tones pursuant to ANSI standards at the receptor locations; and Project- related sound levels at any existing surrounding residences do not exceed 45 dBA(exterior)(Leq)(1 hr) or 30 dBA (interior bedrooms)(Leq)(1 hr).
29. In the event noise from operation of the Project exceeds the maximum allowable levels, Deerfield shall take all remedial steps necessary to bring the sound levels produced by the turbine(s) into compliance with allowable levels, including modification or cessation of turbine(s) operation.
30. Deerfield shall submit to the [Commission] for review and approval a noise monitoring plan to be implemented during the first full year of operation. The plan shall establish a monitoring program to confirm under a variety of seasonal and climactic conditions compliance with the maximum allowable sound levels described above.

This report describes a monitoring plan that meets the conditions of the CPG.

2.0 FIRST YEAR MONITORING PLAN

2.1 | MONITORING CONTRACTOR

A State of Vermont agency will select and supervise a contractor to conduct the sound monitoring, subject to the Commission's approval. The minimum qualifications shall be:

- Experience with short-term attended and long-term sound compliance monitoring at wind projects.
- Experience with cold-temperature sound monitoring.
- Experience with the methodologies outlined in this Protocol.
- Board Certification through the Institute of Noise Control Engineering.

Costs for the sound monitoring contractor shall be borne by Deerfield Wind LLC.

2.2 | DURATION AND FREQUENCY

Each of the two seasonal monitoring periods shall be a continuous period at least two weeks in duration, and meant to capture a variety of meteorological and seasonal conditions. Each monitoring period can be extended for up to 5 weeks in total if necessary to client sufficient valid data to determine Project-only sound levels.

In selecting the monitoring periods, the following shall be considered:

- Whether turbines will be out of service, the length of the outage, and whether the combination of the location of the turbines and length of outages would substantially affect the results of the sound monitoring.
- Whether forecasted heavy rains or storms comprise more than 50 percent of the first two-week period.
- Whether normal operations are expected to be affected by safety concerns, grid reliability, or other issues.

This Protocol acknowledges that many of these factors cannot be forecast in advance with certainty, and therefore the presence of these conditions during monitoring periods may occur despite the best efforts of Deerfield Wind and the sound monitoring consultant. Any departure from ideal monitoring conditions shall be noted in the report.

One period of monitoring will take place during each of spring, and fall, over the first year that the Project is commercially operating. The first year, for the purposes of this monitoring, shall be defined as the first year with two full spring and fall seasons. For example, if construction concludes at the end of spring, the first year will start at the beginning of that fall through the end of spring the next year.

2.3 | MICROPHONE LOCATIONS

Sound monitoring is proposed for three locations, representing unique soundscapes around the Project. As shown on Figure 1 below, Site A is representative of the closest homes along VT 9, and Sites B and C are representative of the closest homes along VT 8.

FIGURE 1: POTENTIAL POST-CONSTRUCTION SITES AND MODELED SOUND CONTOURS BASED ON AS-APPROVED FINAL DESIGN PLANS (SUBMITTED TO PUC ON 6/1/15)

- A) Site A is located south of Old Route 9, east of Bishop Hill Road, and south of VT Route 9 in Searsburg. This area is representative of sound impacts to the north of the Project, and would be as far off of VT 9 as practical. This is

similar in location to Site 2 from the pre-construction monitoring,¹ and is representative of the closest homes and highest sound impacts.

- B) Site B is located near the transmission line that crosses VT Route 8 approximately 1.3 km (0.8 miles) south of the VT 8/VT 9 intersection in Searsburg and west of VT Route 8, and extending north to 149 VT Route 8, just north of the transmission line. This is similar to Site 4 from the pre-construction monitoring, and is representative of the closest homes to the east of the project.
- C) Site C is located approximately 0.5 miles north of Sleepy Hollow Road on VT Route 8 in Searsburg, west of Route 8. This site is roughly equidistant between the Deerfield and Searsburg turbines. The Site includes the two closest homes to the north. This is similar to Site 5 from the pre-construction monitoring, and is representative of the highest combined noise impacts of Searsburg and Deerfield combined.

Monitoring sites are not proposed for the west or south, as there are no nearby homes in these directions, i.e., within a 1.5 mile radius. Beyond that distance, the modeled sound levels are generally less than 30 dBA, and thus do not present a reasonable likelihood of exceeding the CPG sound limit.

Where monitoring locations are near residential areas, to the extent permission is granted, monitors shall be set near individual homes closest to the Project at these locations. If permission is not granted, then alternative homes shall be contacted, or monitors will be placed in public rights-of-way that are representative of a home, at a similar or lesser distance from the Project.

To the extent possible, the sound monitors should be located away from roads to avoid background sound contamination. However, the setback distance from roads should still be representative of the closest home or homes.

Up to three additional monitoring locations may be selected in response to noise complaints made prior to the beginning of the last monitoring period, provided any such addition location is materially different than the locations already being monitored, and that it is within the 30 dBA (exterior) contour.

¹ RSG, "Revised Noise Impact Study for: Deerfield Wind Project, Searsburg/ Readsboro, VT," November 2007 (Exhibit DFLD-KK-4)

Final monitoring locations will be selected by the sound monitoring consultant. When the sites have been selected and the consultant has conveyed them to Deerfield Wind, Deerfield Wind shall file a map with the Commission showing these monitoring, turbine, and met tower locations.

2.4 | LOGISTICS

The location of the microphones shall be chosen on site and based on the following list of site condition priorities:

- 1) Microphones shall be located at least 7.5 m from any surface where reflections may influence the measured sound pressure levels. Microphones shall be placed in a location to avoid potential noise contamination from sources such as flowing water, wind chimes, air conditioners, noises from homes, etc.
- 2) Microphones shall be placed at a height approximately 4 to 5 feet above grade.
- 3) Microphones shall not be placed such that any structure blocks the line of sight between the microphone and wind turbines (if otherwise visible).
- 4) The Contractor will make every reasonable effort to site microphones in a manner that will maximize the probability of capturing the maximum noise levels at each monitoring location, taking into account all relevant factors such as minimizing line-of-sight obstructions between microphones and the Project, and maximizing the number of turbines in line-of-sight of the microphones at each monitoring location.
- 5) Appropriate wind screens should be used. For long-term monitoring in windy conditions, seven-inch hydrophobic wind screens or equivalent should be used.

In some cases, these limitations may mean that the best monitoring location for a specific residence may be several hundred feet away from the primary residential structure. Every effort shall be made to ensure that locations selected are representative of the noise exposure at subject homes.

Sites will include meteorological instrumentation logging data in no more than 10-minute increments, which can include one or more of the following:

- Anemometer (all sites)
- Wind vane (one site)
- Temperature sensor (one site)
- Rain sensor (one site)

All sound level meters will meet IEC Type 1 or better specifications for accuracy, and will be calibrated before and after each measurement period. All monitors will collect 1/3 octave band data from 20 Hz to 10 kHz at one-second logging intervals and audio recordings where permission is granted by the property owner. To protect the privacy of neighbors, audio

recordings shall be released to the PUC upon request and only under a confidentiality agreement or with permission of the homeowner. In all cases, the user of the audio may not disclose the content of private conversations that may have been inadvertently captured.

2.5 | OUTSIDE TO INSIDE TEST

Sound tests of turbine operations will be limited to exterior measurements. This is because the 30 dB interior limit established by the PUC is sufficiently low that the sound test is easily contaminated by normal activities that occur indoors. In addition, frequent sound monitoring inside a bedroom is intrusive. To minimize the impact to residents, interior sound levels will be calculated based on a fixed 15 dBA reduction. However, the homeowner will be given the option to allow for testing to be conducted to determine the actual outside to inside noise reduction (OINR) of the house, if that home meets the following criteria:

- 1) The preconstruction sound model shows Deerfield Project sound levels of 40 dBA or higher at that location; or
- 2) Sound monitoring (post-construction) shows Deerfield Project sound levels of 40 dBA(Leq)(1 hr) or higher at that location.

Deerfield Wind shall offer OINR testing to homeowners who meet Criterion 1 at the outset of commercial operations, and to homeowners who meet Criterion 2 based upon the first year of post-construction monitoring.

An OINR test is used to establish the noise reduction from the outside to the inside of a house. The test will be conducted in accordance with ASTM Standard E966-10, *Standard Guide for Field Measurement of Airborne Sound Insulation of Building Facades and Façade Elements (2010)*.² Any deviations from the standard necessitated by field conditions will be detailed in the report. The OINR test will be limited to a single fully-furnished occupied bedroom facing the Project at each home.

If a homeowner who meets one of these criteria initially declines OINR testing, an attenuation of 15 dBA will be assumed. However, if a homeowner who initially declined OINR testing subsequently files a complaint, that homeowner shall again be offered OINR testing at Deerfield's expense.

Tests will be conducted if permission is granted by the homeowner, with windows closed, one quarter open, and fully open. The sound monitoring consultant should ask the

² The E966 standard is copyrighted. For those who wish to review the standard, but not purchase it, one can be made available for review at RSG offices.

complainant about their window opening patterns throughout the year, and should use the complainant's response as the basis for the window-position assumption.

2.6 | BACKGROUND SOUND MEASUREMENTS

To accurately measure the sound level of the wind turbines, background sound levels must be excluded. This will be accomplished by turning off wind turbines at regular intervals. Turning off wind turbines allows a direct comparison between periods with and without turbines operating.

During the measurement program, the turbines will be shut down for 20 minutes at a time no less once per night (10 pm to 7 am) where hub height wind speeds are at 6 m/s or above, in order to ensure that the turbines would be operating at or near their maximum sound output before and after each shutdown (assuming the wind conditions remain relatively constant over that period). It is understood that wind speeds may change considerably around the shutdown times and may not be consistently high among all turbines. A greater number of turbine shutdowns may occur, with turbine shutdowns to occur as needed in order to collect sufficient turbine-off data needed to accurately determine background sound levels.

Individual contaminating events may be manually filtered or otherwise removed from the data set. These events include, but are not limited to traffic passbys, insects, property maintenance, gunshots, land clearing, voices, etc. This is described further in Section 3. Insects and birds may also be filtered by subtracting out sound at and above 1.6 kHz (a.k.a., “Ai” weighting).

The sound engineer conducting the testing may modify the background sound methodology for good cause. If such modification is made, a description of the good cause and the modifications that were made shall be included in the sound monitoring report.

2.7 | ATTENDED MEASUREMENT

For one hour before or after at least one turbine shutdown event, attended monitoring will take place at each monitoring location. Attendants will make time-stamped notes as to what they hear and the relative loudness of those sounds, including but not limited to wind turbine sound, wind, anthropogenic, and biogenic sounds.

3.0 DATA PROCESSING

Data during some periods will be removed from the results. These include periods when:

- Wind speeds (average or gusts) at a monitoring site are above 4 to 5 m/s – Winds above 5 m/s create a large amount of false noise generated from pressure fluctuations around the microphone. Data for wind speeds between 4 and 5 m/s (or below, as needed) should be carefully reviewed to identify any wind contamination that creates pseudo-noise or wind-induced noise that is sufficient to mask wind turbine sound prior to its inclusion in the filtered data set.
- The temperature is below 14°F – The ANSI S1.4 standard, “Specification for Sound Level Meters,” does not require the provision of temperature corrections below -10°C (14°F) and above 50°C (122°F). As such most sound level meters are not calibrated outside this range. If sound level meters are certified for use below 14°F, this restriction will not apply.
- Rain is present – Rain, sleet, ice, or similar events that drop precipitation onto the microphone windscreen create false noise. Snow events will not be excluded because they do not create false noise.
- Spikes are present that are not consistent with wind turbine operation. Note that this screening is only required for sound levels over 40 dBA, as manual filtering can be time-intensive. Periods that were screened should be identified in the report.

Certain background sounds such as insects and birds can be filtered by employing a low pass filter without affecting the sound monitored from the wind turbines. If these types of sources are found, a low-pass filter may be used, consistent with that described in “Proposed ‘Ai’-weighting; A weighting to remove insect noise from A-weighted field measurements”, Paul D. Schomer, Ian M. Slauch, and George F. Hessler, *InterNoise Proceedings*, Volume 221, pp. 3991-4000 (2010).

Events over 40 dBA (i.e., 5 dBA lower than the CPG exterior noise limit) where the hub height wind speed is sufficient to generate within 1 dB of the maximum sound power (over a reasonable period of time and number of turbines), and the wind direction is not upwind of the nearest turbines shall be investigated by listening to the audio tape or reviewing the spectrogram of the event and determining if the cause is wind turbine noise. If the exceedance is due to a background event, then it shall be eliminated. Events not meeting these criteria may still be investigated on a case by cases basis – for example, to compare modeled to monitored sound levels at a particular location.

Any substantial change in wind speed (or other background sound conditions) between the background and turbine-on monitoring periods shall be evaluated to assess its effect on the calculation of turbine-only sound level. Corrections may be applied as appropriate.

Where background sound levels are within 3 dB of the adjacent measured Turbine-on sound levels, the background and Turbine-on periods will be excluded from further processing

The Turbine-only sound level for the monitoring period will be determined by logarithmically subtracting the energy-averaged background sound level for all remaining measurement periods from the energy-averaged measured Turbine-On sound levels for all remaining measurement periods. This value will be used to compare to the appropriate CPG limits.

For the purposes of compliance with the 45 dBA exterior and 30 dBA interior standards, and other thresholds described in this protocol, all results will be rounded to the nearest whole integer.

At least two valid hours of Turbine-On data will be needed to determine compliance. Note that if five weeks of data monitoring are completed before two hours of valid data are collected, the monitoring period will be concluded, and the available valid periods will be used for compliance determination.

Tonal sounds will be assessed using the criteria of ANSI S12.9 Part 4 Annex C using 1/3 octave band for each rolling measured Turbine-On $L_{eq(1-hour)}$. Rolling periods will be incremented every 10 minutes. If tonal periods are found, then background sound levels can be removed or other methods employed to determine whether the tonality is due to the operation of the Project.

The sound monitoring report will include a description of each reason why data has been removed from monitoring results. The removed data will be retained by the sound monitoring consultant and provided to the Commission.

4.0 REPORTS

A report shall be prepared by the sound monitoring consultant for each monitoring season. Each monitoring report shall include:

- A description of any changes in Project operation made since the last report, special operating conditions, or turbine maintenance issues found during the test procedure.
- Layout of the project area, including topography, project boundary lines for the project and property lines delineating properties surrounding the project site.
- Locations of the sound measurement points with photographs and GPS coordinates of the microphones.
- Distance between any sound measurement point and the nearest wind turbine.
- A summary of all data collected, including sound levels, meteorological data at the monitoring stations, and turbine operating conditions.
- Times of potential exceedances of the outdoor, indoor, or tonal standard, and the results of investigations into those exceedances.
- Conclusions.
- An appendix containing 10-minute data for each turbine including wind speed, and electrical output.

If cold-weather-certified sound monitors are not used, then for the winter season, a report addendum will be prepared which includes sound levels during periods when the temperature is below 14°F. The sound monitoring consultant may include in its reports any information that it believes suggests that the sound level meters are not producing accurate data during times when the temperature falls below 14°F.

Reports shall be submitted to the PUC and the docket parties within six weeks of the end of each monitoring period. Any confidential information (i.e., audio files near residences) will be provided only after executing an appropriate protective agreement. If audio files are provided without a protective agreement, then private conversations will be redacted prior to release. The public versions of the reports (i.e. without such confidential information) will also be provided to the Forest Service.

If it is found that the Project sound level at any existing permanent structure for human habitation is above the allowable limit, Deerfield Wind shall take all remedial steps necessary to bring the sound levels produced by the turbine(s) into compliance with allowable levels, as required by the CPG. Such steps may include engineered solutions, operational changes or adjustments, or legal agreements, as applicable.

5.0 COMPLAINT RESOLUTION

The following complaint resolution procedure will assure that concerns by neighbors regarding wind turbine noise are addressed in a timely manner while, at the same time, preventing abuse of the complaint process. The complaint resolution procedure shall be as follows:

- 1) The complaint process shall be in place for the life of the Project.
- 2) Complaint phone numbers and contact persons for both Deerfield Wind and the Department of Public Service (“DPS”) shall be provided to the Town Clerks and Selectboards of Searsburg and Readsboro, and neighbors within the 30 dBA contour line of Figure 1 existing at the time of the issuance of the CPG.

Complaints may be made to Deerfield Wind by calling (866) 318-9858 or by sending a written complaint to the Deerfield Wind Project, 37 Putnam Road, Searsburg, VT 05363.

Complaints may also be made to the DPS Consumer Affairs and Public Information Division (“CAPI”) under its CPG Complaint Protocol by the following means:

VT Department of Public Service, CAPI Division
112 State Street
Montpelier, VT 05620-2601

E-mail: psd.consumer@vermont.gov

Consumer Hotline: (800) 622-4496

TTY: (800) 734-8390

Fax: (802) 828-2342

Web: <http://publicservice.vermont.gov/cpg-complaint-protocol>

- 3) Deerfield Wind will provide an initial acknowledgment to complaints within two business days of it being notified of the complaint.
- 4) Complainants who contact Deerfield Wind will be asked to provide the following information related to the complaint:
 - a. Location of the observed sound
 - b. Time(s) and date the sound occurred
 - c. Weather conditions (snow cover, cloud cover, wind direction and relative speed, etc.)
 - d. Description of the sound
- 5) Deerfield Wind may ask complainants to log sound events to help identify factors that affect the sound.
- 6) Deerfield Wind shall record the complainant information, and weather, turbine operating status, and power output during the time of the complaint. The Forest Service, PUC, and DPS will be informed of complaints along with these data.

- 7) If the complaint concerns an unidentified icing condition or mechanical problem, Deerfield will investigate as needed and take appropriate action if warranted. Once it is determined that either no aberrational condition exists or the condition is fixed, Deerfield will notify the complainant with a description of Deerfield's findings. Otherwise, no further complaint resolution steps need be taken. Deerfield will maintain files concerning such complaints and make these available to the PUC or DPS upon request.
- 8) Deerfield Wind will investigate as described below if the complaint represents permanent structure for human habitation existing at the time of the CPG issuance and within the 30 dBA contour shown on Figure 1.
- 9) Sound monitoring may be conducted in response to a complaint within the 30 dB contour if the sound level is within 5 dB of the exterior sound limit, based on sound modeling or upon order of the Commission in response to a complaint.
- 10) Sound monitoring may also be conducted if first-year or any subsequent Commission-ordered compliance monitoring during normal operating conditions (defined below) showed that a monitoring location within one mile of the complainant's home showed higher sound levels (with contaminating events filtered out) than what was modeled, to the extent that if this adjustment were applied to the complainant's home, the sound level would be within 5 dB of the exterior limit. For example, if sound monitoring at Location A showed that the maximum sound level is 39 dBA compared to modeling at that location of 38 dBA, then 1 dB would be added to the modeled sound levels of all other homes within a mile of Location A. If that adjustment raises the modeled sound level of a complainant's home over 40 dBA, then that complainant may be offered sound testing at the expense of Deerfield Wind.

Normal operating conditions would not include temporary maintenance issues, short term abnormal turbine operations, or other correctable or corrected conditions at the Project. If such abnormal conditions are the cause of the noise complaint, noise monitoring shall not be required. Deerfield Wind will make any necessary corrections to the Project as soon as feasible and shall communicate the situation to the complainant, Forest Service, PUC, and DPS.

- 11) If Deerfield Wind's sound consultant determines that follow-up sound monitoring is warranted under either Section 8 or 9 above, Deerfield Wind will notify the DPS in writing. The State of Vermont shall contract for and supervise the sound monitoring consultant. The State's sound monitoring shall begin as soon as possible, but no later than six weeks thereafter. All reasonable efforts shall be made to conduct such monitoring under conditions similar to those existing at the time the complaint arose.
- 12) The sound monitoring consultant shall work with the complainant to determine an appropriate location for the monitoring equipment.
- 13) Sound monitoring will follow the applicable protocols from Sections 2.4, 2.6, 3.0, and 4.0, above. Note that the responding noise control engineer may revise aspects of this Protocol to address specific conditions and limitations. For example, if the complaint occurs to the north of the Project along VT 9, then the noise control

engineer can limit the turbine shutdown to the western array as the eastern array would not materially affect the overall sound levels in that area. The basis for any deviations from this Protocol shall be described and substantiated in the test report.

- 14) The primary method for determining the attenuation value of a complainant home shall be OINR testing. OINR testing will be offered to complainants at Deerfield Wind's expense if the conditions for sound monitoring in Item 9, above, are met. The monitored exterior sound level will be converted to an interior level based on the ASTM E966 test result at the home. If permission is not granted for outside-to-inside testing, the attenuation value will be 15 dBA.
- 15) Because of the complexity of complaint resolution, full cooperation of the complainant and the adherence to the above test procedures is necessary.
- 16) The results of the monitoring shall be contained in a report that is submitted to the complainant, Deerfield Wind, the Department of Public Service, Forest Service, and the PUC. This report will contain specific information collected during the complaint monitoring, including wind speed and direction, operational status of the turbines, sound levels, and the raw sound level data collected by the noise control engineer conducting the tests. Allegedly confidential information will be treated the same as in Section 4 of this protocol.
- 17) If no exceedance is found at a location, including during the first-year monitoring, the location would be exempt from additional sound monitoring for five years.
- 18) Nothing in this Protocol would prevent Deerfield Wind from appealing to the PUC from relief in the cases of alleged frivolous, harassing, or repeated unsubstantiated complaints.

If it is found that the Project sound level at the complainant residence is above the allowable limit, Deerfield Wind shall take all remedial steps necessary to bring the sound levels produced by the turbine(s) into compliance with allowable levels, as required by the CPG. Such steps may include, but are not limited to, engineered solutions, operational changes or adjustments, including partial, temporary, or permanent shutdowns or noise-reduced operating modes, or legal agreements, as applicable.

APPENDIX B – FALL 2018 MEASUREMENT PLAN

TECHNICAL MEMORANDUM

Prepared for: Geoffrey Commons
Special Counsel
Vermont Public Service Department
112 State Street
Montpelier, VT 05621-2601

Prepared by: Douglas Barrett, Cross-Spectrum Acoustics Inc.

Subject: Noise Monitoring Plan for Deerfield Wind Project – FINAL -- Revised

Reference: CSA Project No. J2018-1170

Date: October 17, 2018

Cross-Spectrum Acoustics Inc. (CSA) has been retained by the Vermont Department of Public Service (DPS) to provide sound monitoring expert services in relation to compliance testing for the Deerfield Wind Project located in Searsburg and Readsboro, VT. Two periods of noise monitoring, one during the fall of 2018 and one during the spring of 2019, are to be performed in accordance with the “Final Sound Monitoring Protocol for Deerfield Wind”¹ (Protocol). This memorandum provides the detailed plan to conduct the fall 2018 measurements.

1. OVERVIEW OF MONITORING REQUIREMENTS

This section provides an overview of the monitoring requirements as provided in the Protocol. *Please note that this is intended only to provide an overview of the monitoring program and that the Protocol should be consulted to obtain all relevant information.*

1.1. Monitoring Periods: Each of the two monitoring periods shall be a continuous period at least two weeks in duration, but may be extended for up to five weeks if necessary to obtain sufficient data. In selecting the monitoring period, consideration shall be given to whether:

- Turbines will be out of service, length of outage, and whether the locations of turbines and length of outages would “substantially affect the results of the sound monitoring.”
- Forecasted heavy rains or storms comprise more than 50% of the two-week period.
- Normal operations are expected to be affected by safety concerns, grid reliability, or other issues. (Protocol, Section 2.2)

¹ “Final Sound Monitoring Protocol for Deerfield Wind,” prepared for: Deerfield Wind, LLC, prepared by: RSG, January 16, 2018.

1.2. Monitoring Locations: Sound monitoring is proposed for three locations, as described in the Protocol. Section 2 of this monitoring plan provides further information on specific sites. (Protocol, Section 2.3)

1.3 Outside to Inside Noise Reduction Testing: Outside to inside noise reduction (OINR) testing of houses may be requested by homeowners if that home meets the following criteria:

- The preconstruction sound model shows Deerfield Project sound levels of 40 dBA or higher at that location; or
- Sound monitoring (post-construction) shows Deerfield Project sound levels of 40 dBA (Leq) (1 hr) or higher at that location. (Protocol, Section 2.5)

1.4 Background Sound Measurements: Background sound levels will be excluded by turning off wind turbines at regular intervals, thus allowing a direct comparison between periods with and without turbines operating. To accomplish this, turbines will be shut down for 20 minutes at a times no less than once per night (10 pm to 7 am) where hub height speeds are at 6 m/s or above. A greater number of turbine shutdowns may occur, with shutdowns to occur as needed to collect sufficient turbine-off data. (Protocol, Section 2.6)

1.5 Attended Measurement: For one hour before or after at least one turbine shutdown event, attended monitoring will take place at each monitoring location. Attendants will make time-stamped notes regarding what they hear and the relative loudness of those sounds. (Protocol, Section 2.7)

2. MONITORING SITES

2.1 Proposed Sites: Section 2.3 of the Protocol describes the three proposed sound monitoring sites. “Revised Noise Impact Study for Deerfield Wind Project”² (Noise Study) provides further details on the monitoring sites used during the preconstruction noise measurements. As described in the Protocol:

- Site A is located south of Old Route 9, east of Bishop Hill Road, and south of VT Route 9 in Searsburg. This site is similar in location to Site 2 from the preconstruction monitoring.
- Site B is located near the transmission line that crosses VT Route 8 approximately 1.3 km (0.8 miles) south of the VT 8/VT 9 intersection in Searsburg and west of VT Route 8. This site is similar to Site 4 from the preconstruction noise monitoring.
- Site C is located approximately 0.5 miles north of Sleepy Hollow Road on VT Route 8 in Searsburg, west of Route 8. This site is similar to Site 5 from the preconstruction monitoring.

2.2 Alternative Sites: Section 2.3 of the Protocol states “where monitoring locations are near residential areas, to the extent permission is granted, monitors shall be set near individual homes closest to the Project at these locations. If permission is not granted, then alternative homes shall be

² “Revised Noise Impact Study for: Deerfield Wind Project, Searsburg/Readsboro, Vermont,” prepared for: Deerfield Wind, LLC, prepared by: RSG, November 28, 2007.

contacted, or monitors will be placed in public rights-of-way that are representative of a home, at a similar or lesser distance from the Project.”

2.3 Final Site Selection: Final monitoring sites are to be selected by the monitoring consultant (CSA). When the sites have been selected, the consultant must convey them to Deerfield Wind, and Deerfield Wind will file a map with the Commission showing monitoring, turbine, and meteorological tower locations. (Protocol, Section 2.3)

The attached technical memorandum “Final Monitoring Sites for Deerfield Wind Project -- Revised” (dated October 17, 2018) provides the final locations of the monitoring sites expected to be used for the measurements.

3. MONITORING EQUIPMENT

3.1 Required Equipment: The following instrumentation is required for the monitoring program:

- Three sound level meters (IEC Type I or better) with seven-inch hydrophobic windscreens. CSA expects to service the sound level meters every two days; therefore, each meter must have battery capability to run for at least two days and memory capability for continuous audio recording and one-second logging of 1/3 OB data. CSA’s NTi XL2 sound level meters will meet these requirements.
- Three complete battery sets for each sound level meter (nine total). This will allow for one battery set in use plus a replacement set in E. Longmeadow and a replacement set in Keene for each meter.
- Meteorological monitoring equipment: three anemometers, one wind vane, one temperature sensor, one rain sensor. Equipment must be battery-powered and capable of storing 10-minute interval data.
- Six tripods to support microphones and anemometers four to five feet above ground level.
- Three laptops or other means for time-stamping observations during attended monitoring.

3.2 Equipment Preparation: The sound level meters and meteorological instrumentation will be programmed and otherwise prepared for field use in CSA’s E. Longmeadow office the week before the measurements are to begin (week of October 8).

4. FIELDWORK

4.1 Prior to starting measurements:

- D. Barrett, in coordination with H. Singleton, will conduct the initial site survey, finalize candidate measurement sites, and start the process to obtain permissions.
- Prior to starting measurements, coordination with Deerfield Wind will be required regarding:
 - Site access
 - Development and submittal of the measurement site map (as described in Section 2.3 of the Protocol)
 - Coordination of nightly 20-minute shut-down periods

- Ensuring that turbine data (10-minute data for each wind turbine, including wind speed and electrical output) are saved during the measurement period.
- For audio recordings, CSA must obtain permission from property owners prior to starting measurements.
- H. Singleton and J. Montoya will program and prepare the instrumentation in CSA's E. Longmeadow office.

4.2 During measurements:

- J. Montoya and D. Barrett will meet at the project site and perform initial on-site deployment of equipment. J. Montoya will transport equipment from E. Longmeadow.
- After the initial set-up, either J. Montoya or D. Barrett will visit the project site every two days to service the equipment (i.e. download data and replace batteries).
- One night during the measurement period, J. Montoya and H. Singleton will make an additional trip from E. Longmeadow for attended monitoring. This monitoring session will coincide with one of D. Barrett's scheduled site visits. The exact date will be determined, in part, by weather.
- During the monitoring period, CSA will screen data after each download (according to Section 3.0 of the Protocol) until it is confirmed that at least two hours of good "turbine-on" data have been recorded at each site. J. Suits will be on-call to do this during the monitoring period in coordination with D. Barrett and H. Singleton. Note that measurements may continue for up to five weeks if sufficient data have not been obtained.
- At the conclusion of monitoring, J. Montoya and D. Barrett will meet at the project site and collect the equipment.

5. PROPOSED SCHEDULE

- Conduct site visit, select sites week of September 24 (D. Barrett).
- Prepare and program equipment week of October 8 (H. Singleton and J. Montoya).
- Deploy equipment week of October 22 (aim for Monday, October 22, weather permitting) (J. Montoya and D. Barrett).
- Conduct attended monitoring week of October 29 (pick specific night depending on weather) (H. Singleton, J. Montoya, and D. Barrett).
- If all goes according to schedule, collect equipment on November 5 (J. Montoya and D. Barrett).

TECHNICAL MEMORANDUM

Prepared for: Rob Batarags, Matt Becker, Melissa Fisher
Avangrid
Prepared by: Douglas Barrett, Cross-Spectrum Acoustics Inc.
Subject: Final Monitoring Sites for Deerfield Wind Project -- Revised
Reference: CSA Project No. J2018-1170
Date: October 17, 2018

On October 1, 2018 and October 16, 2018, Cross-Spectrum Acoustics (CSA) conducted site visits to the project site in Searsburg, VT. The purpose of the site visits was to field check the candidate sites included in our memorandum of September 26, 2018 ("Candidate Monitoring Sites for Deerfield Wind Project") and to select the three final sites to be used in both the fall 2018 and spring 2019 monitoring periods.

The three final sites were selected based upon the guidance in the "Final Sound Monitoring Protocol for Deerfield Wind"¹ (Protocol); conditions on the ground, including distance from local noise sources such as roads and accessibility; and the ability to gain permission from property owners. For each site, Table 1 provides a general description of the location, the approximate latitude and longitude of the site, the property owner, and other relevant notes. CSA has contacted each property owner and has been granted permission to conduct noise monitoring at the proposed location.

Figure 1 provides an overview map showing the general location of each site. Figures 2, 3, and 4 show the specific proposed location of each site. Although it is CSA's intention to install the monitoring equipment as close to the locations shown as possible, conditions on the ground at the time of deployment may require minor modifications.

Table 1. Final Monitoring Sites

Monitoring Site	Location	Lat./Long.	Owner	Notes
Site A	South of Old Route 9 and VT Route 9	42.890904 -73.000301	James Bartleson	House shown in aerial imagery no longer present
Site B	197 VT Route 8	42.88178 -72.97244	Gerry DeGray	Clearing to south side of house and driveway
Site C	343 VT Route 8	42.87274 -72.97124	Tom Shea	Edge of graded area south of barn

APPENDIX D – SOUND MEASUREMENT INSTRUMENTATION

This appendix provides a list of all sound monitoring equipment used during the spring 2019 monitoring program.

Site A (CSA “White” Kit)

Sound Level Meter: NTi Audio, XL2, SN A2A-06790-E0

Preamplifier: PCB 426E01, SN 039747

Microphone: PCB 377B02, SN 153679

Calibrator: Larson Davis CAL200, SN 4956

Site B (CSA “Blue” Kit)

Sound Level Meter: NTi Audio, XL2, SN A2A-06977-E0

Preamplifier: PCB 426E01 SN 016981

Microphone: PCB 377B02, SN 125988

Calibrator: Larson Davis CAL200, SN 8477

Site C (CSA “Purple” Kit)

Sound Level Meter: NTi Audio, XL2, SN A2A-14423-E0

Preamplifier: PCB 426E01, SN 053838

Microphone: PCB 377B02, SN 135993

Calibrator: Larson Davis CAL200, SN 4126

Site C-alt (CSA “Yellow-Prime” Kit)

Sound Level Meter: NTi Audio, XL2, SN A2A-15479-E0

Preamplifier: PCB 426E01, SN 060454

Microphone: PCB 377B02, SN 311519

Calibrator: Larson Davis CAL200, SN 16858

APPENDIX E – WIND TURBINE DATA

This appendix provides 10-minute wind speed and electrical output data for each of the 15 Deerfield Wind turbines for the period from May 17 through June 8. This range of dates is the complete set of data provided by Avangrid and includes all turbine-operation curtailments conducted during the spring 2019 monitoring program.

Please note that the times shown in this appendix denote the end of each 10-minute interval.

NOTE REGARDING TIME ZONES:

The data in this appendix were provided by Avangrid's operations center in Oregon with times referenced to Pacific Daylight Time (PDT). All other times show in the report are in the Project's local time, Eastern Daylight Time (EDT). To convert times in this appendix to local time at the Project site, add three hours.

Date/Time	Turbine Power Output (kW)																Turbine Wind Speed (m/s)

APPENDIX F – ATTENDED MEASUREMENT OBSERVER LOGS

This appendix provides the observer logs from the attended measurements which were conducted from 10:00 PM on May 21, 2019 until 1:45 AM on May 22, 2019. During the attended measurements, two turbine-operation curtailments occurred. The appendix provides the logs from Sites A, B, and C in that order.

Deerfield Wind Compliance Monitoring
CSA J2018-1170

Date: May 21 - May 22, 2019
Site: A
Personnel: J. Montoya

Note: "1" indicates loudest (dominant) source, "2" indicates secondary (audible) source

Summary:

Airplane 1 = 34 seconds 85 milliseconds
 Airplane 2 = 4 minutes 0 seconds
 Car/truck 1 = 32 minutes 1 second
 Car/truck 2 = 2 minutes 6 seconds
 Insects/birds 2 = 1 hour 35 minutes 38 seconds
 Other = 3 minutes 3 seconds
 Turbines 1 = 1 hour 16 minutes 41 seconds
 Turbines 2 = 16 minutes 7 seconds
 Wind 1 = 33 minutes 36 seconds
 Wind 2 = 11 minutes 32 seconds

Observation Date/Time		Noise Source		Duration		
20190521	22:03:33	Wind	1	4 seconds	235	milliseconds.
20190521	22:03:47	Wind	1	3 seconds	418	milliseconds.
20190521	22:04:09	Wind	1	3 seconds	181	milliseconds.

**Deerfield Wind Compliance Monitoring
CSA J2018-1170**

Date: May 21 - May 22, 2019

Site: B

Personnel: H. Singleton

Note: "1" indicates loudest (dominant) source, "2" indicates secondary (audible) source

Summary:

Aircraft 1 = 53 seconds 903 milliseconds
Aircraft 2 = 5 minutes 29 seconds
Car/truck 1 = 3 minutes 33 seconds
Car/truck 2 = 2 minutes 5 seconds
Insect/birds 1 = 3 seconds 400 milliseconds
Insect/birds 2 = 2 minutes 58 seconds
Turbines 1 = 1 hour 0 minutes 57 seconds
Turbines 2 = 1 hour 46 minutes 49 seconds
Wind 1 = 1 hour 37 minutes 59 seconds
Wind 2 = 2 hours 8 minutes 48 seconds

Observation Date/Time		Noise Source		Duration			
20190521	21:59:51	Turbines	2	12	seconds	833	milliseconds.
20190521	21:59:51	Wind	2	12	seconds	816	milliseconds.

**Deerfield Wind Compliance Monitoring
CSA J2018-1170**

Date: May 21 - May 22, 2019

Site: C

Personnel: D. Barrett

Note: "1" indicates loudest (dominant) source, "2" indicates secondary (audible) source

Summary:

Aircraft 2 = 2 minutes 8 seconds
 Birds/Insects 1 = 33 seconds 935 milliseconds
 Birds/Insects 2 = 2 hours 28 minutes 53 seconds
 Car/Truck 1 = 3 minutes 40 seconds
 Car/Truck 2 = 36 seconds 79 milliseconds
 East Turbines 1 = 1 hour 20 minutes 47 seconds
 East Turbines 2 = 2 hours 19 minutes 36 seconds
 Other 2 = 30 seconds 293 milliseconds
 West Turbines 1 = 10 minutes 0 seconds
 West Turbines 2 = 2 hours 51 minutes 50 seconds
 Wind 1 = 1 minutes 40 seconds
 Wind 2 = 9 minutes 9 seconds

Observation Date/Time		Noise Source		Duration			
20190521	22:02:06	West Turbines	1	9	minutes	30	seconds.
20190521	22:02:18	East Turbines	2	9	minutes	16	seconds.

APPENDIX G – EXCLUDED DATA: INITIAL FILTERING

This appendix provides the results of the initial filtering of each curtailment attempt to determine viable intervals for further filtering and analysis. This filtering, or screening, was conducted using data collected at the Site B weather station (temperature, precipitation, wind speed, and wind direction) and data from the wind monitors at Site A and Site C (wind speed and wind direction). Section 3.3.2 of the report describes the overall filtering process in greater detail.

Table G.1 provides the screening results for each of the 22 curtailments attempted during the five-week measurement period. For each curtailment, the table shows the six 10-minute “turbine-on” intervals immediately preceding the curtailment (i.e. up to one hour before) and the six 10-minute intervals immediately following the curtailment (i.e. up to one hour after). Note that although the “turbine-off” periods were nominally 20 minutes, the actual durations varied. In addition, there were transition periods while the turbines were shut down and when they were restarted. For these reasons, the time elapsed between the one-hour “turbine-on” periods before and after each curtailment may vary.

For each 10-minute “turbine-on” interval, the table shows whether the interval was excluded or included for further analysis. If the interval was excluded, the table provides the disqualifying factor. These include the following:

- “Wind Direction” was the most common reason for exclusion of data. This indicates that there was an upwind vector component to the nearest turbines for at least a portion of the 10-minute interval.
- “Weather (precipitation)” indicates that rain was recorded at the Site B weather station during at least a portion of the interval. Relatively few periods were excluded for this reason because Avangrid attempted not to conduct curtailments during periods of precipitation.
- “Wind Speed > 5 m/s” indicates that the maximum wind speed *at the measurement site* exceeded 5 m/s for a substantial portion of the 10-minute interval. In cases where the wind speed was greater than 5 m/s for a smaller portion of the interval, the period was carried forward, but flagged for further analysis during the secondary filtering of data. (This exclusionary criterion should not be confused with the requirement that *hub-height* wind speeds were at least 6 m/s during the curtailments.) In addition, although not shown here, intervals with wind speeds between 4 m/s and 5 m/s were flagged for further screening.
- As required by the Protocol, the data sets also were screened for temperatures below 14° F, although no temperatures that low were recorded during the spring 2019 measurements.
- Because the measurements at Site A and Site B concluded before those at Site C, some intervals are labeled “Measurement Concluded” for those two sites.

The 10-minute intervals that were not excluded for any reason during the initial filtering are identified in the table with the word “Include.” These intervals were carried forward for further filtering as described in Appendix I.

APPENDIX H – EXCLUDED DATA: ADDITIONAL FILTERING, “TURBINE-OFF” PERIODS

This appendix provides the additional filtering analysis conducted for each of the “turbine-off” intervals carried forward after the initial filtering described in Appendix G. Based on the initial filtering, for some of the 22 curtailment attempts, no “turbine-on” intervals at any of the measurement sites qualified for further analysis. For other curtailment attempts, viable 10-minute intervals were identified at one, two, or all three measurement sites. For any curtailment when at least one viable 10-minute “turbine-on” period was identified, the adjacent “turbine-off” period was evaluated at the corresponding measurement site or sites.

This appendix provides the analysis for each curtailment attempt which qualified for further filtering. For each curtailment attempt, at each applicable measurement site, the following are included:

- A graph showing the 1-second sound level time history during the “turbine-off” period. On each graph, the sections identified with a lighter blue line show periods that were excluded due to contaminating events such as traffic on nearby roads, aircraft overflights, all wind gusts exceeding 5 m/s, and some wind gusts below 5 m/s. Other natural sounds, such as frogs, insects, and birds, typically were filtered by applying ANS-weighting (see Section 3.3.4). For the sites and curtailments where ANS-weighting was used, the graphs show the ANS-weighted sound level, as indicated on the graph. The darker blue line sections on each figure indicates the periods that remained after filtering and that were used to compute the “turbine-off” L_{eq} for the curtailment.
- A table with entries corresponding to each excluded period shown on the graph, along with the reason for excluding the data. In some cases, the tables include events that were examined but not excluded from the data set.

The appendix is organized with the graphs and tables in order by curtailment number.

APPENDIX I – EXCLUDED DATA: ADDITIONAL FILTERING, “TURBINE-ON” PERIODS

This appendix provides the additional filtering analysis conducted for each of the “turbine-on” intervals carried forward after the initial filtering described in Appendix G. For each curtailment attempt with viable periods for further analysis, the following are included:

- A graph showing the entire 1-second sound level time history starting one hour before the beginning and extending to one hour after the curtailment’s “turbine-off” period. For curtailments when ANS-weighting was used, this graph shows the ANS-weighted sound level for the entire period.
- A table with entries corresponding to each period that was excluded during the additional filtering, along with the reason for excluding the data. The most common events excluded were traffic on nearby roads, especially at Site A due to its proximity to VT Route 9. Other contaminating events included aircraft overflights, all wind gusts exceeding 5 m/s, and some wind gusts below 5 m/s. As with the “turbine-off” filtering described in Appendix H, other natural sounds, such as frogs, insects, and birds, typically were filtered by applying ANS-weighting (see Section 3.3.4 of the main report). In some cases, the tables include events that were examined but not excluded from the data set.
- A table showing the computed L_{eq} and residual time for the remaining portion of each 10-minute interval after all filtering. The filtered L_{eq} for the adjacent “turbine-off” period is shown in a red font immediately above this table. Any of the “turbine-on” intervals that exceed the “turbine-off” L_{eq} by at least 3 dB are highlighted in green. The green-highlighted values met all screening criteria and, therefore, were included in the computation of the overall “turbine-on” L_{eq} for that measurement site. Any “turbine-on” intervals not exceeding the adjacent “turbine-off” L_{eq} by at least 3 dB were not included in the final computations (see Section 3.3.2 of the main report for additional details). In cases where the table indicates that an entire 10-minute interval was excluded by the weather screening described in Appendix G, no L_{eq} is shown for that interval.
- Graphs showing the 1-second sound level time histories during each of the 10-minute “turbine-on” periods extending one hour before and one hour after the turbine curtailment. The graphs with red-shaded title blocks indicate 10-minute intervals that were excluded by the initial weather screening described in Appendix G. Although the graphs are provided here, the sound level data from these intervals were not included in the analysis. The remaining graphs, with green-shaded title blocks, include data that passed the initial screening. On each graph, the sections identified with a lighter blue line show periods that were excluded either due to contaminating events (corresponding to the entries in the preceding the tables) or not meeting weather screening requirements. The darker blue line sections on these figures indicate periods that remained after the additional filtering and that were used to compute the “turbine-on” L_{eq} for the interval.

The appendix is organized with the graphs and tables in order first by measurement site, and then by curtailment as follows:

- Site A, Curtailment Numbers 1, 2, 4, 5, 13, and 18.
- Site B, Curtailment Numbers 1, 2, 3, 9, 10, 11, 12, and 13.
- Site C, Curtailment Numbers 1, 2, 4, 13, 16, 17, 18, 19, and 22.
